Lévi-Strauss chose to study the gathered corpus of the Amerindian myths. He finds out that the many different Indian cultures developed very particular myths, which at the same time are remarkably homologous with respect to each other. It is so, Lévi-Strauss tells us, because they are the fruit of a single human mind. It is because there are some fundamental, not categories, but differentiations. That is to say, there are fundamental building bricks prior to conceptualization. His thesis is that myths represent the first and most profound expression of the human mind. Myths can be said to be consubstantial with the mind. The same goes for language in its constitutive form, which is why the way myth and language operate have so much in common. The human mind, or rather a mechanism proper to the human mind, generates the structure of myths, as well as the structure of language. Lévi-Strauss confronts us with a multiplicity of levels that strangely enough only make sense in their relations and transformations. This huge network of permutation and transfer works on its own. No human transmitting the myths from generation to generation is actually conscious of the mechanism. No one is aware of what goes on and of how it works. Lévi-Strauss points out that it is as if the myths think by themselves. Somewhat, myth as such does the talking.

Thus, the concept of myth in Lévi-Strauss's work does not so much refer to a specific kind of story relating to the origins of the world, people, languages, rituals, and such things. No, for Lévi-Strauss, myth is a fundamental and original category of the human mind, to which a specific way of thinking corresponds, namely mythic thought, which proceeds by successive dichotomies and oppositions. It is because of this universality of mind, that one can identify redundant themes and similar fundamental oppositions in the stories told in all different cultures. By studying the appearance, disappearance, and replacement of certain themes in favor of others, Lévi-Strauss did show that myths make use of oppositions between sensitive categories promoted to logic, a logic that matters as least as much as 'reality.'

Lévi-Strauss's corpus of myth is made of more than 800 myths taken from dozens of different Amerindian tribes across the two Americas. Thus, for instance, in the first of the five volumes of *Mythologiques*, he looks into how the 'raw-cooked' dichotomy – which relate to the opposition between nature and culture – operates in various myths (Lévi-Strauss, 1986(1964)). Mythic thought, he explains, reduces reality by means of a specific binary logic of oppositions, and it is so because its own rule of functioning has to build upon such a kind of binary code. This is why one finds similar ways of arranging the world into myths in so many different cultures. This is why myth and thought can be said to be independent of contingent historical conditions.

In his seminal introduction to the work of Lévi-Strauss, Marcel Hénaff, stresses the importance of the mechanisms proper to the human mind in the generation of the structures of the human myths, and why according to Lévi-Strauss one should not look for a social origin of symbolism, but rather for a symbolic origin of the social: "The intelligibility that there is in institutions and organizations comes not from the social as such but from the fact that the collective systems has the required content, and it is because it has that content that the social is possible" (Hénaff, 1998(1991): 119).

This of course does not mean that myths are transcendental in nature; to the contrary. Because this mind and this binary logic come from the materiality of the human brain, "myths signify the mind that evolves them by making use of the world of which it is itself a part" (Lévi-Strauss, 1986(1964): 341).

Structuralism, Not Determinisn

Lévi-Strauss tells us that "structural arrangements are not a pure product of mental operations" (Lévi-Strauss, 1985(1983): 117). He emphasizes the importance of the senses: "The eye does not merely photograph the outside world. It rather encodes its formal characteristics. These characteristics consist less in the sensuous qualities of things than in the relationships which prevail between them" (Lévi-Strauss, 1973: 20). He notes that atoms, molecules, cells, organisms, and the sense organs also function structurally. He points out that the mind continues to work out structurally a material that it has received structured. And that "it can only do so if the mind, the body to which the mind belongs, and the things perceived by body and mind are part and parcel of one and the same reality" (Lévi-Strauss, 1985(1983): 117).

Organisms do rely on internal interactions and do interact. It does not imply only one world to be possible. Likewise, Lévi-Strauss pointing at the binary logic emerging from the materiality of the human brain does not imply an absolute determinism. He knows that societies evolved differently and could have evolved differently. Brain proposes, society disposes. He is more interested at pointing out the fact that, "however variable the rules may appear when we compare societies, they include constant elements, which are interpreted differently or which differ only in their application" (Lévi-Strauss, 1978(1973): 70).

Lévi-Strauss does not intend to deduct all further social development from the origins of language and culture. He just shows that equipped with symbolic language humans are related to their world, unconsciously making use of distinctions and oppositions related to their sensory abilities. He also explains that such building bricks of sense making will always be in use in human minds and cultures even though the whole system and every subsystem obviously ended up mingling into something very complex. As Maurice Godelier points out:

> By revealing the existence of mental constraints and forms of sociability common to all humanity, Levi-Strauss shows that the cultural and social diversity in time and place, does not exclude but rather presupposes the universality of core structures of the human mind. Therefore, absolute relativism does not make sense because, beyond what distinguishes and separates cultures and forms of society, the same mental structures and patterns of sociability remain present and active in all societies and at all times. Thus each society is a unique combination of universal and specific structures, which do not oppose each other. They don't because the universal structures are the condition of existence of the specific ones and also the distinctive form they take as social realities.
>
> Godelier, 2013: 62; my translation

Too many introductions to Lévi-Strauss work tend to reduce his structuralism to a determinism ignorant of historical factors. In fact, Lévi-Strauss stresses that history from the very beginning introduced intrinsic modifying elements into the underlying original, never fully completed symbolic system. He points out that "a society is always spatial-temporal given, and therefore subject to the impact of other societies and of earlier states of its own development" (Lévi-Strauss, 1987(1950): 17–19). He emphasizes that even in hypothetic isolated societies, "the different systems of symbols which all combine to constitute the culture or civilisation would never become reducible to one another" (Lévi-Strauss, 1987(1950) #24987: 17). The translation of one system into another happens at different paces and within a network. In other words, the translation is "conditioned by the introduction of constants with values external to the two systems" (Lévi-Strauss, 1987(1950): 17).

Cultural Diversity and the Unity of Humanity

According to Lévi-Strauss, "anthropology should not be reduced to the study of relics to be sought close to home or far away. What matters above all is not the archaism of these forms of life but their differences from one another and from those that have become our own" (Lévi-Strauss, 1978(1973): 29). The purpose of anthropology is not so much to discover the

unique characteristics of societies but in what they differ from one another. "As in linguistics, it is the *discontinuities* which constitute the true subject matter of anthropology" (Lévi-Strauss, 1972(1958): 318).

Lévi-Strauss has "tried to show that the real contribution of cultures does not consist in a list of their particular inventions but in the *contrastive features* which exist between them" (Lévi-Strauss, 1978(1952): 358). Lévi-Strauss points out that "the diversity of human cultures (…) is less a function of the isolation of groups than of the relationships which unite them" (Lévi-Strauss, 1978(1952): 328). He stresses the importance of cultural diversity for the many cultures and the whole civilization, which, as he sees it, consists of the coexistence of cultures. World civilization, he says, "could not be anything on the world scale except the coalition of cultures, each preserving its originality" (Lévi-Strauss, 1978(1973): 358).

Thus Lévi-Strauss has always stressed the inanity and vanity of condescension as well as contempt. His seminal UNESCO lecture from 1952 (Lévi-Strauss, 1978(1973)) is one of the greatest monuments ever erected not only against racism of any kind (biological and cultural) but also against arrogance. In this lecture entitled *Race and History*, he analyzed the notion of progress and showed that no objective criteria could be provided for a comparison and evaluation of human societies. Cultural progress is not due to the superiority of a specific society but to each culture's aptitude in establishing mutual exchanges with the others. Just like humans and other living beings do, cultures rely on each other. Lévi-Strauss often stressed that the dominating Western civilization would not have turned up to be what it is today if it had not been confronted by other cultures that made its members think differently. In Europe, the Crusades, Marco Polo's long visit to China, the Ottoman invasions, the progress of geographical exploration, fed cultural inspiration, and anthropological reflection (Lévi-Strauss, 2013(2011): 7–9). It is worth noticing that the Renaissance rediscovered forgotten notions and methods in ancient literature. However, more important still, "it realized the means of putting its own culture in perspective – by confronting contemporary concepts with those of other times and other places" (Lévi-Strauss, 1978(1973): 272); an intellectual method Lévi-Strauss called the "technique of estrangement" (Lévi-Strauss, 1978(1973): 272). Already then, it was known that "no fraction of humanity could aspire to understand itself without reference to all the other human beings" (Lévi-Strauss, 1978(1973): 272), that "no civilization [could] define itself if it does not have at its disposal some other civilization for comparison" (Lévi-Strauss, 1978(1973): 272).

Nevertheless, humanism was then still restricted in many ways. The types of cultures known were geographically limited. The classic civilizations had disappeared. The interest in the Middle and Far East applied only to their most scholarly and refined productions. Appropriate anthropological methodologies were still lacking to study civilizations without written documents 'discovered' in the Americas. Last but not least, classical humanism was also restricted in its beneficiaries and linked to industrial and commercial interests. Little by little, ethnological knowledge of other customs that astonish us, shock us, or repel us called ourselves into question, and invited us "to temper our misplaced vanity, to respect other ways of life" (Lévi-Strauss, 1978(1973): 36–37). Constructed in dialogue with different scientific traditions, anthropology revealed that "every custom, every belief, however shocking or irrational it may appear to us when we compare it to our own, is part of a system whose internal balance has been established over the course of centuries" (Lévi-Strauss, 1978(1973): 44). Furthermore, Lévi-Strauss means to have shown "that one cannot eliminate an element from the whole without running the risk of destroying all the rest" (Lévi-Strauss, 1978(1973): 44).

Since his visit to the Bororos, Nambikwaras, and Tupis in the late thirties, Lévi-Strauss has been very much concerned with a lack of understanding: that of the diversity and unity of mankind. Not only does it have disastrous consequences for the so-called 'primitive' people whom he clearly showed were at least as intelligent, clever, and skilled as we are, but in a different way, it also threatens our species and our planet with extinction. Economic growth and globalization might lead to societal blight. The diversity, so vital to any form of life, decreases. Lévi-Strauss is concerned about the biosphere, but also about cultural diversity. He tells us that those two problems are related. As cultures exchange, their differences diminish and might come to the point of disappearing and there will not be much more to exchange. This might weaken humanity as it has to cope with the challenges of a decrease in biological diversity. So, "both the absence and the excess of communication have their dangers" (Lévi-Strauss, 1958: 149; Lévi-Strauss, 1961(1952): 206–207). Thus, one of the most prominent fighters against racism of all time dares criticize the dangers of a naïve and blind form antiracism that does not take into account the lessons of social anthropology. Value relativism and multiculturalism have their limits. He stresses that cultures can exhibit greater or lesser affinity with other cultures – a fact of history and a normal behavior that should not be confused with racism (Lévi-Strauss, 1958: 150; Lévi-Strauss, 1961(1952): 209). Here is what he has to say on this:

> Humanity must learn (…) that all true creation implies a certain deafness to the appeal of other values, even going so far as to reject them if not denying them altogether. For one cannot fully enjoy the other, identify with him, and yet at the same time remain different. When integral communication with the other is achieved completely, it sooner or later spells doom for both his and my creativity. The great creative eras were those in which communication had become adequate for mutual stimulation by remote partners, yet was not so frequent or so rapid as to endanger the indispensable obstacles between individuals and groups or to reduce them to the point where overly facile exchanges might equalize and nullify their diversity.
>
> Lévi-Strauss, 1985(1983): 24

Of course, an oversimplified understanding of this point provided an opportunity for a few politically right-thinking people to feel some self-satisfaction. Lévi-Strauss's contribution is relevant when discussing cultural relativism, an issue that has gained importance lately. Lévi-Strauss clearly shows that all and each human being is never totally imprisoned within his or her own cultural bubble. By showing this, Lévi-Strauss denies the very possibility of cognitive relativism. Individually and collectively, you are bound to evaluate and compare. Not wanting to take a look outside or trying to render your bubble opaque implies values and comparisons. Thus,

cultural and cognitive relativism are in fact self-refuting. They are also almost antiscientific as they tend to render anthropological or historical work meaningless.

More generally, it is somewhat paradoxical that not so few intellectuals criticized Lévi-Strauss for things he neither did or said. Choosing to see in his structuralism a negation of the subject and in his critique of the excess of communication a new form of intolerance is misleading. His focusing on the principles at work in social systems does not imply an ignorance of the importance of individual reflection and engagement. Lévi-Strauss greatly contributed to ethics, politics, and tolerance. He seriously and sincerely dared to ask all the questions he thought ought to be asked in relation with the knowledge and challenges of his time. He criticized a form of philosophy (like that of Sartre) that "cuts itself off from scientific knowledge which it despises, as well as from human reality, whose historical perspectives and anthropological dimensions it disregards, in order to arrange a closed and private little world for itself" (Lévi-Strauss, 1981(1971): 640). According to him, too much of philosophy was still reflecting in ways that did not take into account the prodigious developments of science and the alarming development of global society. Still, as he turned his back on philosophy to dedicate himself to social anthropology, he ended up contributing to it. Of course many of his theories can be criticized. As an example, regarding his theory of the elementary structures of kinship, Lévi-Strauss indicated that the reason men ruled the exchanges of women was a natural one (which does not imply that culture cannot develop against this original stand). It is most likely that there were social reasons for this: women had to cope with the fact that men had the monopoly of violence. One could of course call this a natural difference. Nevertheless, out of this necessity of sexual collaboration and uneven distribution of strength, heavy tools, weapons, and violence, one can identify a principle other – and maybe even more fundamental – than that of the rules of kinship. In these sharing of roles and power that are most likely to have preceded symbolic language, one might find a fundamental principle at the very basis of all social life, and one that does not have to proceed directly from the structure of the mind: the principle of reciprocity, of sharing. Basic relations of exchange are also experienced in nonhuman societies. For example, the behavior of chimpanzees and bonobos are now mentioned as examples of how humans might gradually and simultaneously have developed their brain, language, relations, and tools resulting in the ability to postpone their actions and exchanges. Thus, as Godelier points out: "it is not from the unconscious that the principle of reciprocity arose out of, but from 'our way of being in the world'" (Godelier, 2013: 125). This implicit obligation of reciprocity, Godelier says, "is immanent to the fact that no one can ever exist without society existing and that no individual can ever develop her or his hidden potentials without society's permission" (Godelier, 2013: 125). Society provides or refuses the means.

And there are other relevant and constructive critiques that can and have been made of the work of Lévi-Strauss. Most of them somehow are in the same vein as his: trying to unveil human nature and the nature of human relations. What is most striking about Lévi-Strauss's theoretical models is the powerfulness of the footbridges and springboards they constituted. It is "his ability to theorise complex phenomena in such a way as to bring out their relevance for an understanding of other kinds of phenomena" (Wiseman, 2007: 17).

One of the main characteristics of Claude Lévi-Strauss was his ability to ask new questions and combine information in a new way. His work will continue to inspire many a scientist from many a discipline. Also, through his work, the almost forgotten wisdom of societies practically eradicated still provides us with ideas that might help us relate to ourselves and our planet.

> The human groups thus designated [as primitive] are for the most part those that differ from our own by virtues of the absence of writing and mechanization. But we must not forget a few primordial truths about them: these societies provide the only model for understanding how human beings lived together over a historical period undoubtedly corresponding to 99 percent of the total duration of the collective life of humanity. Their existence lasted until recent times (from a geological perspective) and covered three-quarters of the surface of the inhabited earth.
>
> What these societies offer, therefore, are not really lessons about the phases of our distant past. They illustrate rather a general situation, a common denominator of the human condition. Seen from that standpoint, it is the high civilizations of the West and East that constitute exceptions.
>
> Lévi-Strauss, 2013(2011) #24723: 13–14

"Lévi-Strauss explained the vital importance for all human beings – and particularly us – that cultural groups may carry on sending us the message that the historically dominant way of being human today is but one among many" (Lenclud, 2008: 26). He also showed that shared representations evolve and sometimes, for internal and cross-cultural reasons, people end up having to reorganize their system of thought. Today, we may have entered a state of crisis at the global level because of the accelerating pace of globalization.

Not so long ago these representations were not necessarily made explicit and were generally taken for granted: they manifested themselves in institutions that were accepted and made sense. Nowadays, as one commentator of Lévi-Strauss points out: "it is almost as though each cultural group has to constantly build and rebuild its own representations – usually in terms of communication – in order for its ongoing existence – one that is different from all other groups – to be recognised" (Lenclud, 2008: 21, translated from the French).

Abstract

First, the personal and scientific biography of Kurt Lewin is sketched, from his early education in Posen and Berlin, and two semesters (of medicine and biology) in Freiburg and Munich, until the time when Berlin and its university became Lewin's permanent residence, and, where interrupted by the war of 1914 to 1918, he embarked on the first stage of his career, which soon gained international recognition. This recognition turned out to be vital when in 1933 Lewin, as a Jewish scientist, had to leave Germany and found asylum in the USA until his early death in 1947. The academic stations of his US career were Cornell, Iowa, and the MIT. In conclusion, this article reports and assesses Lewin's major research topics, the development of his field theory, and his innovative research style.

Biography

Kurt Lewin was born on 9 September 1890 in Mogilno, a small town in the (then Prussian) province of Posen, now Poland. He was the second of the three children of Leopold and Recha Lewin who owned a general store and a small farm. Kurt was sent to a *Gymnasium*, a secondary school, in Posen until, in 1905, the whole family moved to Berlin, as did many ascending Jewish families living in the eastern provinces of the Reich and in Eastern Europe.

In Berlin, Kurt Lewin attended the humanistic *Kaiserin-Augusta-Gymnasium*. In 1909 he took up university studies of medicine and biology in Freiburg and Munich, but in 1910 he was back in Berlin to take courses in philosophy and science. His special interest soon became philosophy of science, in which field the (neo-Kantian) philosopher Ernst Cassirer and the psychologist Carl Stumpf were most influential with regard to Lewin's intellectual development. Stumpf, the director of the Psychological Institute and the patron of what was to become the Berlin school of gestalt psychology (*see* Köhler, Wolfgang (1887–1967)), became Lewin's doctoral supervisor.

Since in 1914 Lewin volunteered for the army and soon did service on the Western Front, he was awarded his doctoral degree as a soldier in 1916. While on furlough from the front in 1917, he married Maria Landsberg, a fellow student from prewar days. The same year, 1917, was also the year of Lewin's first two publications, which, in their dissimilarity, indicate the scope of Lewin's interests: a paper on mental activities in the inhibition of processes of volition, based on his doctoral thesis, and an almost phenomenological paper on the 'war landscape,' foreshadowing Lewin's later involvement in ecological problems.

Also predictive for Lewin's further intellectual as well as social development were his extracurricular activities and associations as a student, as from early on he had engaged himself in socialist student groups which took an active interest in the social and, mainly, educational problems of workers in agriculture and industry. From this enduring interest resulted two early publications in 'applied psychology,' one on rationalization in agriculture, one on the socialization of the Taylor system. Many later publications followed as a result of his and other Jewish psychologists' forced emigration to the USA.

Before the war ended Lewin was severely wounded and hospitalized. Decorated with the Iron Cross and promoted to the rank of lieutenant, he was discharged from military service.

In the following years, Lewin, who had returned to the Psychological Institute of Berlin University, and received his *Habilitation* in 1921, became assistant in the new department for applied psychology, a position which he held until his emigration in 1933. In 1927 he was appointed *außerordentlicher Professor* – a title, not a tenured position.

Although in close spatial and intellectual proximity with Köhler's group of gestalt psychologists, Lewin, who concentrated on studies of will, affect, and action, soon gathered a group of young talented students around him, 'whose background was more often than not female, Jewish, and eastern European' (Danziger, 1990: p. 173). Some of Lewin's Berlin women students gained international recognition by their association with Lewin, and some shared his later fate as refugees. But it is fair to say that Lewin's rapidly growing scientific reputation was also due to the works of his doctoral students, which Lewin represented at conventions and in journals, preferably in his own series in the journal *Psychologische Forschung*.

An important date in Lewin's vita was 1929. In this year Lewin, who had separated and divorced from his wife Maria, remarried. His second wife, Gertrud, had been a friend of the family for several years. Professionally, 1929 was the year for which he received an invitation to attend the ninth International Congress of Psychology at Yale. This was shortly after J.F. Brown, an American who had studied with Lewin, had published a paper on 'The methods of Professor Lewin' in the 1929 *Psychological Review*, which had attracted the attention of US psychologists to the work of Lewin's Berlin group. In Yale Lewin impressed his audience with a short paper on environmental forces (read in German) and an equally short, but self-made motion picture of an 18-month-old girl trying to sit on a stone for the first time in her life – one of the many films that Lewin found useful for the graphic representation of the life space (see below). According to G.W. Allport, who had witnessed Lewin's performance in Yale, 'This ingenious film was decisive in forcing some American psychologists to revise their own theories of the nature of intelligent behavior and of learning' (quoted in Marrow, 1969: pp. 50f.). It was his first

encounter with a US audience that resulted in Lewin being invited as visiting professor by Stanford University in 1932.

It turned out that after this stay in Stanford Lewin would only briefly return to Berlin, as in January 1933 the Nazis seized power in Germany. On his return trip from California via Japan and the USSR Lewin decided that he and his family could not live in Nazi Germany. Fortunately, shortly after his return he received a cable informing him that Cornell was inviting him to join the faculty staff, which he gladly accepted – just in time.

From 1933 to 1935 Lewin then worked at the Cornell School of Home Economics. In 1935 he was offered a position at the Iowa University Child Welfare Research Station. For 8 years he worked in Iowa as a professor of child psychology. It was in these years that Lewin taught excellent students who became his disciples and, later, colleagues; for example, Barker, Bavelas, Cartwright, Festinger, French, Lippitt, White, and Zander. It was also during this period that Lewin's research interests shifted toward social psychological problems. In 1937 he became one of the founders of the Society for the Psychological Study of Social Issues, whose president he became in 1941.

This social engagement reflects Lewin's increasing concern with the interaction between research and practice which led to his conception of 'action research,' and to the idea and foundation of the Research Center for Group Dynamics at MIT in 1945, whose main research task was to be 'the development of scientific methods studying and changing group life and the development of concepts and theories of Group Dynamics' (quoted in Patnoe, 1988: p. 9).

This institution framed the final period of Lewin's life. In 1947, in the middle of a rather hectic spell of activity, he died of a heart attack, on February 12 in Boston, at the age of 56. In the same year the Research Center moved to the University of Michigan, Ann Arbor, where it still exists as a prominent place of social research.

Research Topics and Fields

Social interaction, mainly in small face-to-face groups, was such a driving force in Lewin's professional life that it is difficult, often impossible, to single out and identify his strictly individual contribution to what the Berlin or Cornell or Iowa or MIT group produced. Conversely, psychological knowledge today owes a great deal to names such as Barker, Cartwright, Dembo, Festinger, French, Hoppe, Karsten, Kelley, Lippitt, Ovsiankina, Pepitone, Thibaut, Zeigarnik (an alphabetical, hence arbitrary, order of students, and colleagues who worked with Lewin). From their oeuvre, whether published individually or as coauthors, whether during Lewin's lifetime or thereafter, it would be difficult to do an auctorial analysis of variance. But it would be futile, too, since Lewin, at least, believed firmly in the creativity of dialogical thinking. Hence, Lewin is not only an author's name, it is also a brand name for products of the interaction between Kurt Lewin and his associates.

If one is looking for a name designating the unity of products from Lewin's groups the choice, after all, would be 'field theory,' which was also Lewin's final preference although for many years the favorite was 'topology.' It has been stated frequently but is useful to repeat that 'field theory is probably best characterized as a method: namely a method of analyzing causal relations and of building scientific constructs' (Lewin, 1997).

The conceptual tools of this metatheory and methodology (rather than theory and method) are found mainly in two monographs (Lewin, 1936, 1938) and two anthologies (Lewin, 1997, 1999). Lewin adopted the philosophical foundation of Ernst Cassirer's (1953) distinction between 'substance' and 'function,' his theory of a historical transition from 'thing-concepts' to 'relation- (or function-) concepts' and from an abstraction- to a construction-mode of concept formation. Lewin applied this conception to psychology in his 1931 paper on the transition from an Aristotelian to a Galileian mode of thought (in Lewin, 1935). For him psychology deals with relations or functions (rather than thing-like entities) which are basically dynamic, i.e., forces.

In accordance with gestalt theoretical principles, every individual psychological instance (experience or behavior) is the result of an interaction of several features of a given whole or situation; ultimately, each behavior is determined by the total situation in which it occurs. For Lewin the total situation was the 'life space' organized by interdependent forces. In other words, the life space is the 'totality of facts which determine the behavior (B) of an individual at a certain moment. The life space (L) represents the totality of possible events. The life space includes the person (P) and the environment (E). '$B = f(L) = f(P, E)$' (Lewin, 1936: p. 216).

It is this formula, which binds person and environment inextricably together, which has become a kind of shorthand for field theory: It is important to note that owing to the principle of interdependence, neither person nor environment is granted independence. The field, which is structured into regions, paths, and barriers, is basically a field of forces (tendencies to change or to resist change). Some regions are attractive to the person (they have a positive 'valence'). Others are repulsive (they have a negative 'valence'). The person is also considered to be a differentiated region with similar structural and dynamic properties.

These formal characteristics of the life space may be sufficient to explain why Lewinian psychology, whether of learning, of memory, of decision, of action, or of social interaction and relations, is intrinsically dynamic and deals with tension systems (as in anger, aggression, regression, substitution, flight into irreality, etc.), with forces affecting the level of aspiration, conflict, decisions, pressure, resistance, and with styles of leadership or the social-emotional atmosphere of small groups. It was mainly the latter type of studies, their designation (of 'authoritarian' vs 'democratic' vs 'laissez-faire' styles of leadership), and, last but not least, the fact that they were published in the early war years, that attracted wide and lively public interest, curiosity, and critique. From these studies, in which things 'happened' that were not designed to happen (such as 'laissez-faire' in lieu of a 'democratic' style), moving toward the use of research for policies of social change, what Lewin has called 'action research,' was but a small, though consequent and innovative step. It was final confirmation for the interdependence that Lewin had postulated between theory and practice, basic research and applied science.

Assessment

A critical assessment of what in the first five decades after Lewin's death has variously been called the Lewin tradition, legacy, or heritage is difficult because this is a multidimensional and multiperspectival task.

It is multidimensional because of the many research fields in which Lewin was engaged, beginning with the general experimental psychology of learning, memory, affect, motivation, and action, through child and personality psychology, to social, mainly small-group psychology, education, and social change, as well as, from the start, metatheory and methodology. It is multiperspectival since, depending on which experts or resources are consulted at any given time, Lewin's influence on present psychology will be differently evaluated.

It may be easy to neglect the temporal or epochal factor. While, in the first two decades after his death, Lewin's or 'Lewinian' theory could rightly be named a 'contemporary systematic framework,' and 'field theory' occupied sizeable chapters in handbooks of social psychology, this situation had begun to change in the 1980s to such an extent that quite a few of the centennial retrospectives due in 1990 were celebrations with reservations (cf Graumann, 1992; Schönpflug, 1992; Wheelan et al., 1990). Field theory was no longer one of the grand theories of (social) psychology (if indeed there were any great ones left). Topology and vector psychology were going out of fashion. Progress in mathematical psychology no longer included topology and hodology as Lewin (1936) had envisaged and practiced them. If Lewin identified himself and has been identified with topology and vector psychology, his significance for contemporary psychology has noticeably decreased. None of his influential disciples, who all remember Lewin drawing 'bathtubs and eggs' in class, has seriously pursued topology as a theoretical and methodological system. But, as outlined above, many of the 'psychological concepts' listed in Lewin's 'Topology' of 1936 have not only survived but become common psychological knowledge.

What is more important for Lewin's heritage and his presence in contemporary psychology is the diversity with which his *oeuvre* has been handed down by his disciples and followers. To name but two traditions which may both rightly be called Lewinian, but in fact have little in common, there is, on the one hand, the prominent group of experimental social psychologists, going back to Lewin's Iowa period (1935–44) and the beginnings of the MIT Research Center for Group Dynamics through Lewin's death in 1947. On the other hand, there is the tradition in which group dynamics and action research have been seen essentially as means of changing human relations, individuals, groups, and societies. The journal *Human Relations,* founded by Lewin in cooperation with the Tavistock Clinic in London, has become an outlet for publications on applied group dynamics from which so-called 'sensitivity training' and resulting 'encounter groups' have gained the broadest notoriety by growing into a movement (cf Back, 1973).

But even if one stays within Lewinian experimental social psychology, the variance of derivations from Lewin's original ideas is considerable. If one looks for the common element, most of Lewin's senior disciples testify that it was Lewin's 'style' and the 'atmosphere' he created around him – a thoroughly Lewinian remark since 'Lewinian style included an appreciation and sensitivity to context – the interplay of person with environment' (Patnoe, 1988: p. 88; cf Graumann, 1992). What Patnoe (1988: p. 15) concluded from the testimonies of Lewin's contemporaries, namely that 'Lewin created his own microculture,' has been taken by historiographers of psychology as an enduring characteristic of Lewin's research style. Mitchell Ash (1995), who as a historian of gestalt psychology (and of other èmigré psychologists after 1933) is interested in the role of milieu changes, states that Lewin, who had already established 'a scientific microculture around him' in Berlin (Ash in Schönpflug, 1992: p. 20), accomplished the same in Iowa. The (sometimes very intense) interpersonal interaction in Lewin's research group was not just different from the methods of the (other) gestalt theorists (Ash, 1995: p. 272). For Kurt Danziger, who has specialized in the history of psychological research, Lewin developed an investigative practice that 'departed fundamentally from the natural scientific model of experimentation' (Danziger, 1990: p. 175). Considering that Lewin's Berlin experiments were not in social but in personality psychology, it is a striking innovation that even here (and in principle) the 'investigative situation is recognized as intrinsically social, and in research on personality it must form part of the object of investigation' (Danziger, 1990: p. 175).

In anticipation of and in accordance with Lewin's later theorizing, the experimental subject is not a decontextualized individual, but a person-in-a-situation, and an important interacting part of the situation is the person of the experimenter. It is here that the Galileian thought and postulate which gave birth to field theory have become instrumental in an innovative, psychologically autonomous research practice – a legacy of Lewin's that psychologists still have to appropriate.

Lex Mercatoria

Christine Windbichler, Humboldt Universität zu Berlin, Berlin, Germany

Published by Elsevier Ltd.

Abstract

The Latin term *lex mercatoria* denotes transnational self-regulation among merchants at least as early as the Middle Ages. Legal scholars disagree about whether historical *lex mercatoria* constituted a legal system. Nowadays, transnational private governance is practiced and expanded. Modern formulating agencies like International Institute for the Unification of Private Law and UN Commission on International Trade Law work out systematic restatements, principles, and internationally standardized trade terms to further worldwide commercial transactions. Governmental and nongovernmental organizations formulate the so-called soft law, that is, guidelines and best practices, to bring about international norms in many areas where no global legislation is available. Historically and currently, parties in international business disputes avoid state courts and prefer arbitration. Arbitration tribunals apply *lex mercatoria*, the theoretical dispute about the qualification of the rules as law notwithstanding. In a global context, the private, self-governing *lex mercatoria* approach is indispensable. Legal scholars and social scientists today are exploring the legitimacy of rules developed by private organizations and the interplay of law and private ordering.

Lex mercatoria, often translated as 'law merchant,' does not really fall within the scope of law in the sense of a government-based legal system. The origins of these kinds of rules are private, autonomous, international, a-national, or transnational. *Lex mercatoria* is not devised by state courts or a state legislative body. Its practical impact, however, has been undisputed since ancient Roman times. Modern *lex mercatoria* is discussed under the auspices of continuing globalization and post-national law.

Historical Development and Current Definitions

In Roman law, *lex mercatoria* was part of *ius gentium* (law of nations), that is, a kind of international law more flexible than the rather rigid Roman *ius civile* (civil law) (*see* Civil Law; International Law and Treaties). *Lex mercatoria* encompassed customary law in international trade. Historically, it is the major root of the consensual contract. However, it is disputed whether Roman *lex mercatoria* as part of *ius gentium* offers a precedent for medieval *lex mercatoria* as a legal system apart from national legal systems (De Ly, 1992).

The medieval *ius commune* was based on Roman *ius civile*. For centuries it had provided a legal framework generally applied in Europe. Legal scholars cultivated a common understanding based on Justinian's *Corpus Iuris*, despite the division of medieval Europe into many more distinct political entities than today, all with their various local laws. In the same vein, medieval *lex mercatoria*, a cosmopolitan mercantile law, developed from transnational customs and practices. For example, merchants copied deeds used for similar transactions. Disputes were settled by market tribunals or special national courts like the English admiralty courts. The English *Carta Mercatoria* of 1303 provided certain foreign merchants with a fast dispute settlement mechanism and application of law merchant (as opposed to feudal law or city law; De Ly, 1992). The English admiralty courts relied on the best sources available, be they domestic or foreign, in elaborating a worldwide maritime law as a subset of law merchant (Juenger, 1995).

In the seventeenth century, English Common Law courts began to apply law merchant by incorporating customary rules developed by traders and used in arbitration or special courts. 'Law merchant' was defined as

> a number of usages, each of which exist among merchants and persons engaged in mercantile transactions, not only in one particular country, but throughout the civilized world, and each of which has acquired notoriety, not only amongst those persons, but also in the mercantile world at large, that courts of this country will take judicial notice of it. (Lethulier's Case (1692) 2 Salk 443 (per Holt, CJ))

This merchant law was less rigid and less formal than the common law but accepted by common law courts, which consequently developed into a forum for commercial litigation. Merchant law with its informal and international roots became common law. The change of label gradually also took away its international character; merchant law became national commercial law. Later codifications of commercial law, for example, the English Sale of Goods Act of 1893 and the American Uniform Commercial Code, are to a large extent restatements of law merchant principles as represented in common law. Today, the term 'merchant law' is often used to mean 'national common law relating to commercial transactions.'

Modern usage understands *lex mercatoria* as an arrangement of standardized clauses and general legal principles; for example, the principle of good faith, applying to international trade and commerce. To set it off from law merchant incorporated in national common law, some authors prefer 'new' or 'modern *lex mercatoria*' or '*new law merchant*' and similar terminology when referring to modern (informal) codifications of transnational commercial law (Hellwege, 2012).

A number of intergovernmental and nongovernmental organizations developed standardized clauses and rules based on extensive comparative studies. Often enough, these rules served as a model for national lawmaking and international conventions. An outstanding example of a formulating agency

is the International Institute for the Unification of Private Law (*Institut international pour l'unification du droit privé*, UNIDROIT), set up in 1926 as an auxiliary organ of the League of Nations. UNIDROIT is now an independent intergovernmental organization with 63 member states. Its purpose is to study the needs and methods for modernizing, harmonizing, and coordinating private and, in particular, commercial law and to formulate uniform legal instruments, principles, and rules. Many of UNIDROIT's drafts have resulted in international conventions, such as the Convention on a Uniform Law on the Formation of Contracts for the International Sale of Goods, which was adopted at a diplomatic conference of the member states in The Hague in 1964. The UN Commission on International Trade Law (UNCITRAL), formed by the UN General Assembly in 1966, also has contract law topics on its agenda. A prominent example is the Vienna Convention on the International Sale of Goods. The International Chamber of Commerce (ICC), founded in 1919 and now represented in 130 countries, provides INCOTERMS® (International Commercial Terms), an important set of clauses in worldwide use last updated in 2010.

Lex mercatoria also refers to unwritten or, at least, not systematically collected principles and clauses that reflect international trade usage or custom (Goode, 1997). Such rules are applied by arbitration tribunals; for example, the ICC International Court of Arbitration, established in 1923. The ICC publishes arbitral awards but does not disclose parties and other sensitive details. Legal practitioners as well as scholars compile and discuss modern *lex mercatoria* based on such arbitral awards. Such reasoned compilations gradually replace unwritten custom. UNIDROIT has prepared a well-researched collection of contract law used in international trade, the *UNIDROIT Principles of International Commercial Contracts*, first published in 1994. These principles intend to spell out rules that are common to many existing legal systems and accommodate the requirements of international trade. The UNIDROIT Principles do not claim to have binding force. They are intended to be applied in practice only by means of their persuasive value. Similarly, in many other fields of law, general principles, guidelines, or best practices are set forth by professional bodies, trade associations, interest groups, legal scholars, and governmental or intergovernmental agencies. Examples are International Financial Reporting Standards (IFRS) of the International Accounting Standards Board, an institution of the independent, not-for-profit private sector IFRS-Foundation. In some instances, like the UNIDROIT project, the objective is to establish an unbiased and well-balanced restatement; in other instances, a political or manipulating impact is intended.

Main Characteristics and Practical Impact of Modern *Lex Mercatoria*

Based on historic development and present-day definitions, the modern *lex mercatoria* can be characterized as transnational, a-national, or even post-national. In the absence of a 'world legislator,' international trade and commerce have developed functional rules based on common practice. Modern ideas of law from the beginning of the nineteenth century assumed that all law must emanate from the sovereign; therefore, the concept of an independent *lex mercatoria* declined (Dalhuisen, 2007). However, parties to a transnational contract tend to avoid national courts and domestic laws that would present imponderables in procedure and substance. In a globalized world, internationally active professionals develop and rely on well-established commercial clauses and norms that enable contracting parties to overcome language barriers and biases. Business people and their lawyers draw from the condensed and standardized experience in their special fields of business. Such standardized usage can be summarized as modern *lex mercatoria*. However, parties or their counsel writing a transnational contract rarely invoke *lex mercatoria* as such. They rather make use of specific clauses and principles. Therefore, the term '*lex mercatoria*' is not actually used in international trade but rather denotes an abstraction.

Usually, agreements of arbitration or other forms of dispute resolution that avoid state courts include references to *lex mercatoria* clauses and principles. Arbitration rules themselves are often part of *lex mercatoria*, too, such as UNCITRAL's, the World Bank International Center for the Settlement of Investment Disputes', or ICC's rules on international commercial arbitration. In the case of *Scherk v. Alberto Culver Co* (417 U.S. 506), the US Supreme Court pointed out the purpose of such arbitration agreements:

> A contractual provision specifying in advance the form in which disputes shall be litigated and the law to be applied is … an almost indispensable pre-condition to achievement of the orderliness and predictability essential to any international transaction. Furthermore, such a provision obviates the danger that a dispute under the agreement might be submitted to a forum hostile to the interests of one of the parties or unfamiliar with the problem area involved.

This case from 1974 is in line with the UN Convention on the Recognition and Enforcement of Foreign Arbitral Awards from 1958, which has been ratified by 148 countries.

Theoretical Analysis

In legal theory, it is disputed whether *lex mercatoria* is 'law.' Proponents of the theory of *lex mercatoria* as an independent body of law (mainly French, English, Dutch, and German scholars) argue on the basis of a functional or sociological concept of law (Stein, 1995). In this line of thinking, an autonomous body of law governing international commerce can exist without a source in state power: "*Il existe un droit dont la source est ailleurs que dans l'Etat*" (Bonell, 1997; Carbonneau, 1990; also Dalhuisen, 2007; Dezalay, 1995; Kahn, 1961; Osman, 1992). However, it would be considered a third category between national and international law.

Other theorists, especially legal positivists, who define law as based on the power of the (nation) state, deny the existence of an autonomous *lex mercatoria*. They argue that the lack of judicial enforceability cannot be substituted by private autonomy, as even contracts need national law to be put into effect. Constitutionalism, positivism, and the concept of the sovereign state are irreconcilable with rule making by private

governance. Additionally, a contract is only conceivable within a legal order; there is no *contrat sans loi* (contract without law).

Furthermore, it is argued that *lex mercatoria* is much too vague, difficult to ascertain, and incomplete to qualify as a legal system. A more recent academic dispute challenges the notion that medieval *lex mercatoria* existed as a uniformly and universally adopted system (Kaden, 2012; Michaels, 2007, 2012). *Lex mercatoria* is called a 'myth,' its proponents 'medievalists' or 'mercatorists'. The larger context of this controversy is the debate about whether private ordering in a globalized world can work independently from government involvement. Hence, the issue of whether medieval *lex mercatoria* was a legal system turns mostly on one's definition of 'system,' which is likely to be subject to sociological overtones (Teubner, 1997; *see* 03183; Law, Autopoiesis in; Legal Systems, Classification of; Luhmann, Niklas (1927–98)).

This academic dispute – whether medieval law merchant is the archetypal sophisticated legal system that private groups can create when not impeded by the intermeddling of the state – is of only limited practical impact. No theoretical question arises when model laws or other products of formulating agencies have been incorporated into national law. Courts apply the resulting statutes, and parties to a contract can refer to such statutes in choice of law clauses. In other cases, when a state is not a signatory or the respective set of clauses is a private convention, courts test the validity of *lex mercatoria* clauses as standard business conditions according to national law. Any international recognition of such clauses gives them a certain dignity and adds to their acceptance. Choice of law clauses that call for the application of *lex mercatoria* as such are rare; the objection of vagueness would then be well argued. Parties to international contracts tend to be specific. Sets of clauses develop and find their way into domestic contracts, too. Standardized private arrangements even dominate financial instruments, especially derivatives, in the financial markets. Terms of stock options, for instance, follow distinct patterns as 'European' or 'American' depending on the dates on which the options may be exercised. Such patterns are designed by custom and practice, not by law.

Arbitration clauses are prevalent in international trade (*see* International Arbitration). An arbitration tribunal is free to apply *lex mercatoria* principles and reach its decision on the equities of the case. The validity of arbitration clauses is generally recognized by state courts, especially if the clause inserted is in accordance with the "Rules of Conciliation and Arbitration" of the ICC, the UNCITRAL rules on international commercial arbitration, or a similarly established procedure (Lando, 1994; Lehmann, 2004).

A different perspective focuses specifically on the nonbinding nature of certain norms. The so-called soft law, such as guidelines, recommendations, codes of conduct, best practices, and so forth, has gained ground in the last few decades. The practical impact and even legal relevance of nonbinding principles can be considerable. The OECD Guidelines for Multinational Enterprises, for example, provide voluntary principles and standards for responsible business conduct consistent with applicable laws (Horn, 1980). Similarly, the OECD Principles of Corporate Governance assist member and nonmember governments in their efforts to evaluate and improve the legal, institutional, and regulatory framework for corporate governance in their countries and to offer guidance and suggestions for stock exchanges, investors, corporations, and other parties that have a role in the process of developing good corporate governance.

Governments and international institutions may discuss sensitive policy issues more freely and have fewer reservations when they enter into agreements that are nonbinding (Dryden, 1999). From the perspective of private parties, guidelines, recommendations, and best practices leave private autonomy formally untouched despite their persuasive authority. If not properly explained, deviation from widely recognized standards can result in loss of reputation with respect to business partners or investors. Compliance with soft law can serve as safe harbor, such as by helping a defendant fend off a claim of negligence. The way to deal with accepted best practices is to 'comply or explain.' Some binding laws honor nonbinding codes and require a declaration of compliance or reasoned noncompliance (examples can be found in the US-American Sarbanes–Oxley-Act, 2002, a law reacting to numerous financial scandals). Noncompliance with informal standards does not lead to legal sanctions but noncompliance with disclosure rules possibly will. Construction of technical legal concepts as, for instance, the business judgment rule, may well draw upon best practices.

Perspectives

Globalization of commerce, information, and other areas of life brings about challenges similar to what ancient Roman merchants and English tradesmen faced and met by establishing *lex mercatoria*. In global commerce, the realities of the borderless world of cyberspace and open financial markets run headlong into geographically delimited national jurisdictions of sovereign states. The attainments of constitutionalism, the nation-state, and the rule of law are limited in a global market. For example, in the environment of electronic communication, private regulation is gradually absorbed or superseded by national law and international conventions. In sports, too, world championships and similar events follow elaborate procedures on the basis of rules that are not law in a formal sense. A worldwide network of sports associations has undisputed jurisdiction over the rules of the game. 'Private ordering' is gaining ground much in the same way *lex mercatoria* established itself as a legal, commercial, or sociological reality. Given the extreme difficulties of global regulation, effective market-driven, self-regulatory mechanisms, assisted by formulating agencies, are possible and desirable. State-based legislation and self-regulation are not incompatible but complementary (Dalhuisen, 2007; Dryden, 1999).

The controversy over whether medieval *lex mercatoria* constituted a system, that is, was internally uniform and externally autonomous, or rather an archipelago of well-established rules in a fluid sea of individual contracts and customs, is theoretical and should not divert us from more pressing issues. One issue is the legitimacy of a rule that is not conferred by contract when it comes to third-party

interests; another is undue influence by biased formulating agencies (Bachmann, 2006). Further research is also needed in the interpenetration of private ordering, binding, and nonbinding law. The adoption of commercial clauses or rules as nonmandatory state law and disclosure requirements for nonbinding practices are examples of such complements.

The history of *lex mercatoria* shows that transnational, nongovernmental regimes can be functional. Modern *lex mercatoria* harmonizes specific fields of law, sets standards in the form of codes of conduct, and provides self-regulation in the absence of a world legislator.

Lexical Consolidation

Jakke Tamminen, Royal Holloway, University of London, Egham, Surrey, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

An extensive body of evidence has emerged over the recent years suggesting that representations of newly learned words continue to develop over the hours and days following learning. This process of lexical consolidation is particularly critical for the integration of new words in the mental lexicon. Work using neuroimaging and sleep methods suggests that this is due to the operation of complementary learning systems in the medial temporal lobe and the neocortex, with the former rapidly generating discrete episodic representations, and the latter slowly integrating the new words with existing information during off-line periods such as sleep.

Adding a new word into your existing store of words, the 'mental lexicon,' seems intuitively like a straightforward task. You need to find out what the new word sounds like, how it is spelled, and what it means. Once you have these pieces of information, you are ready to use the word and to understand it when it is encountered in print or in speech. However, a systematic research effort over the past decade or so has begun to map the many cognitive operations involved in word learning and has revealed some surprising findings. One of the major realizations has been that it is not sufficient to ask what you know about a word. It is also necessary to ask whether the new word has been connected with other components of the language comprehension and production system, as we know familiar words are. This distinction was lucidly made by Leach and Samuel (2007) who termed these processes 'lexical configuration' and 'lexical engagement.' Lexical configuration refers to knowledge of the factual information about a word, such as its spelling, phonology, and meaning. Lexical engagement on the other hand refers to the interaction of the word with respect to other lexical or sublexical units, and measures the degree to which a word has been integrated in the mental lexicon. Recent research into adult word learning has shown that our intuition about word learning being fast and relatively straightforward is more or less accurate relative to lexical configuration: people can indeed memorize new words quickly even with little training. Interestingly, at the same time our intuition is wrong: evidence of lexical engagement is most often seen only when the learner is tested some hours or days after training. It is hypothesized that this delay in the emergence of lexical engagement reflects off-line memory consolidation, a process occurring over time in the absence of further exposure to the new stimuli during which newly acquired memories gradually become stronger, integrated with existing knowledge, and resistant to interference. Here I will describe evidence for lexical consolidation in word learning. I will then outline a theoretical view of the cognitive and neural mechanisms that mediate lexical consolidation, based on the influential complementary learning systems (CLS) accounts of memory (McClelland et al., 1995; Davis and Gaskell, 2009). It is important to note that most of the studies that address the issue of consolidation in word learning come from adult populations, but the emerging evidence suggesting that the same principles apply in children will also be reviewed.

Behavioral Evidence for Lexical Consolidation

Consolidation appears to be critical for lexical engagement. One example of lexical engagement is seen during the process of recognizing a spoken word. As the spoken signal gradually unfolds, listeners entertain several hypotheses about the identity of the word (Marslen-Wilson, 1987). Hearing the first few sounds of a word will activate a cohort of competing word candidates matching the incoming signal. As the ensuing lexical competition continues and as more of the signal is heard, the number of matching candidates is reduced until only one remains. The point at which only one word matches the signal is known as the uniqueness point. The uniqueness point affects the word's recognition time: words with an early uniqueness point are recognized faster than words with a late uniqueness point. Lexical competition is a good example of lexical engagement, an instance of interaction between lexical units and hence a potentially reliable test of lexical integration of novel words.

Gaskell and Dumay (2003) exposed participants in a phoneme monitoring task to meaningless spoken novel words, and sought to examine whether these novel words engage in lexical competition with existing words. To this end, the novel words were derived from existing base words with relatively early uniqueness points (e.g., *cathedruke* derived from *cathedral*). Lexical competition effects were tested by measuring lexical decision and pause detection times to the base words. Both tasks are thought to index lexical activity of the lexical competitors. The authors found that being exposed to *cathedruke* slowed down response times to *cathedral*, not immediately after exposure, but only in a delayed test session several days later. Explicit form knowledge, a measure of lexical configuration, was tested in a two-alternative forced choice recognition memory task requiring discrimination between trained novel words and similar sounding untrained novel words. Highly accurate performance was found immediately after training, with only a slight improvement with time. The lexical decision and pause detection data showed that newly acquired words engage in lexical competition with existing words only after a period of consolidation while the forced choice data showed that the form of the novel words had been acquired to a high degree immediately after training. Together these data suggest that

novel words integrate in the mental lexicon after consolidation. The time course of lexical integration was further narrowed down by Dumay et al. (2004) who showed that lexical competition effects can be observed as soon as 24 h after exposure. Tamminen and Gaskell (2008) retested eight months after initial exposure and still found lexical competition effects in a lexical decision task. This was interpreted as evidence against an argument that the lexical representations created in these experiments might be only transient and not as well established as words learned outside the laboratory environment.

It is plausible that the effects of lexical consolidation in these word learning studies could be an artifact of repeated testing following training. Perhaps the lexical competition effects emerged as a function of increasing practice with the test task? This potential confound was eliminated in a study reported by Davis et al. (2009) who modified the testing procedure so that only one testing session was required. Participants learned one set of novel words on day 1, and another set on the following day. Testing took place immediately after the second training session on day 2. Hence one set of novel words had been learned on the previous day, and had a chance to be consolidated prior to testing. As expected, the consolidated set showed lexical competition effects despite the fact that only one testing session occurred. The unconsolidated set did not show competition effects.

These lexical competition effects are not limited to learning new spoken words. Many models of written word recognition postulate a similar mechanism of competition where orthographic neighbors, such as *banish* and *vanish*, inhibit each other's activation (McClelland and Rumelhart, 1981). Bowers et al. (2005) taught participants novel words which, if lexically integrated, should become competitors with existing 'hermit' words, that is, words with no prior neighbors (e.g., *banana* and the novel word *banara*). Novel words showed weak inhibitory effects immediately after training and strong effects one day later. This finding replicates the lexical consolidation effect with weak immediate effects and strong effects one day later, with no additional training in between (although cf. Qiao et al., 2009).

The data reviewed so far are usually interpreted as demonstrating the generation and consolidation of a new lexical entry. However, this interpretation is complicated by the fact that in all of these studies the novel words have been close variants of existing words (e.g., *cathedruke* vs *cathedral*). This means that it is unclear whether consolidation in these studies operates on new lexical representations. It might be the case that what is being learned and consolidated is either a new variant of an existing lexical entry or an episodic memory trace of the novel word. In the latter case, lexical competition effects might arise after consolidation due to the novel episodic memory trace being activated by exposure to the closely related real word (e.g., *cathedral*), and this activation diverts attentional resources which may cause slowing of responses to the base words. These alternative accounts were addressed by Dumay and Gaskell (2012) who trained participants on novel spoken words that fully embed the base word, such as *lirmucktoze*. Here the familiar base word *muck* is far less noticeable than in the onset overlapping novel words discussed so far. Competition effects were found one day and week after training but not immediately after training, thus replicating the lexical consolidation effects obtained in earlier studies. Dumay and Gaskell (2012) tested the episodic account with a different task of lexical engagement: word spotting. In word spotting, participants are asked to spot spoken words such as *mess* in carrier sequences such as *domess*. The typical finding is that if the carrier sequence is compatible with a familiar word, then word spotting times are slowed down (e.g., *domess* being compatible with *domestic*), and this reflects the inhibition of the short embedded word (*mess*) by its longer competitor (*domestic*). Applied to word learning, the logic is that spotting *muck* in *lirmuckt* should be slower if participants have previously learned *lirmucktoze*. If lexical consolidation is needed for lexical engagement, this inhibitory effect should emerge only after a delay. The episodic account makes the opposite prediction. If what is being consolidated is an episodic memory trace, then word spotting times should speed up over time as a strengthening episodic trace should help phonetic decoding of the carriers. The data however showed facilitation immediately after training, which turned into inhibition after consolidation, supporting the view that initial episodic lexical representations become integrated in the lexicon over a period of consolidation. Also, a two-alternative forced choice task and a free recall task both showed improved performance after consolidation.

Integrating novel word forms with familiar word forms in the mental lexicon is not the only type of integration newly learned words must undergo, as there are other types of linguistic knowledge that the words need to be integrated with. One important example is semantic knowledge. Integration of a novel word in existing semantic stores of knowledge should manifest as the novel word affecting the activation of other semantically related words or concepts. One example of such interactions comes from experiments where printed words can slow naming times of semantically related pictures when the two are presented simultaneously or with a very short stimulus onset asynchrony (i.e., picture–word interference). Clay et al. (2007) showed that presenting a novel word simultaneously with a picture, slowed picture naming times relative to presenting an untrained nonword, and this effect was observed immediately after training. This general picture–word interference effect however does not imply that the meaning of the novel word has been learned, as the same effect is observed when any real word is presented with a picture, regardless of the semantic relationship between the items. Crucially, presenting a novel word simultaneously with a semantically related picture slowed naming times relative to presenting an unrelated novel word. This effect was not observed immediately after training, but only a week later. These data suggest that a lexical representation can be created very quickly (the source of general picture–word interference). However, generation of a semantic representation able to exert picture–word interference required a period of consolidation, suggesting that lexical consolidation is necessary for integrating novel words with existing semantic networks.

Tamminen and Gaskell (2013) addressed the same issue using semantic priming. In semantic priming the processing of a word (e.g., *doctor*) is facilitated by previous exposure to

a semantically related word (e.g., *nurse*). Such effects are usually interpreted as reflecting automatic spreading of semantic activation amongst related words (McNamara, 2005). Therefore, Tamminen and Gaskell (2013) reasoned that if a novel word becomes integrated in existing networks of semantic knowledge, they should come to prime semantically related existing words. This was found to be the case, both when the novel word prime was presented long enough to be consciously accessed, and when it was presented very briefly and masked so that participants had little conscious awareness of it. This masking procedure is important because it implies that the spread of activation was automatic rather than influenced by response strategies. The priming effect did not emerge immediately after training on the novel words, but only after a week's consolidation opportunity. Together these semantic priming data and the picture–word interference provide strong evidence that lexical consolidation does not operate only on representations of word forms, but also in their integration with semantic knowledge.

We have seen that lexical consolidation is necessary for integrating new words with existing lexical knowledge of word forms and meanings. What about the influence of novel words on phonological knowledge? Snoeren et al. (2009) demonstrated compensation for place assimilation with newly learned spoken words. Place assimilation refers to the finding that in continuous speech certain word-final consonants change according to the properties of the first consonant of the following word (e.g., the /n/ in *lean bacon* is often assimilated with the following /b/, resulting in *leam bacon*). Listeners however perceive the assimilated phoneme as an instance of the canonical form, in other words they compensate for assimilation. This compensation is typically not found in assimilated nonwords, suggesting that the effect is lexically driven. In Snoeren et al. (2009), participants learned novel words ending in /t/ or /n/ (e.g., *decibot*), and were later exposed to a test phase where the assimilated form of the words were presented in a spoken sentence (e.g., *the decibo[p] behaved badly*) in a phoneme categorization task. Participants did indeed show compensation with the newly learned words but not with untrained nonwords, suggesting that there is significant top-down lexical involvement in perception of assimilation, and that only trained novel words had acquired enough of a lexical status to allow for compensation for assimilation to operate. This was the case for words tested immediately after training and one day after training. However, phoneme categorization responses at test were faster for the words learned the day before testing, suggesting that consolidation facilitated access to the phonological form of the novel words.

Lindsay et al. (2012) used the Ganong effect as a tool for measuring the degree with which novel words can bias phonemic categorization. The Ganong effect refers to the finding that in a phoneme categorization task listeners interpret an ambiguous phoneme that could equally well be /d/ or /t/ (henceforth /?/) as more /d/-like when presented in *?ash* than in *?ask*, because *dash* is a familiar word while *dask* is not (Ganong, 1980). If newly learned words can exert a similar lexical influence on phonemic categorization, this would suggest that they enjoy a similar lexical status to familiar words. Lindsay et al. (2012) trained participants on novel words that ended in a /d/ (e.g., *confald*) or did not end in a /d/ but instead had an untrained regular past tense inflected form that would end in /d/ (e.g., *confal* whose past tense inflected form would be *confalled*). At test, participants carried out a phoneme categorization task on *confal?*. The results showed an immediate bias toward interpreting /?/ as /d/ in these novel words, showing consolidation-independent lexical influences in phonological processing, just like in Snoeren et al. (2009). However, the size of this effect increased over a week of consolidation. In addition, phoneme categorization response times to test items where the final phoneme was not ambiguous (e.g., *confald*) became faster over the week, suggesting that access to novel word phonology is facilitated by consolidation.

Neuroimaging Evidence for Lexical Consolidation

The consolidation effects probably reflect a change over time in how novel words are represented, and therefore effects of consolidation should also be detectable in how these words are represented in the brain. Davis et al. (2009) used functional magnetic resonance imaging (fMRI) to discover the neural structures mediating processing of consolidated novel words (learned the day before scanning) and unconsolidated novel words (learned shortly before scanning). Here the primary measure of lexical integration was the neural response to consolidated novel words, unconsolidated novel words, untrained novel words, and real words. An elevated response to unconsolidated and untrained novel words compared with real words was found in a bilateral region of the superior temporal gyrus, and also in bilateral motor cortex, supplementary motor area, and cerebellum. Interestingly, this difference was not found between the consolidated novel words and real words, suggesting that only consolidated and not unconsolidated novel words were mediated by the same neural structures as real words. When a contrast was made between consolidated, unconsolidated, and untrained novel words, a region of interest encompassing the hippocampus showed higher activation to untrained than unconsolidated words in the first scanning run. This suggested that the untrained novel words, which had never been heard before, engaged the hippocampus upon their first exposure. This activity declined in the following two scanning runs, and became similar to activity elicited by trained novel words. Magnitude of hippocampal activity on the first run was also positively correlated with later recognition memory of the novel words in a two-alternative forced choice task.

A similar pattern of hippocampal activity was reported by Breitenstein et al. (2005). Participants learned novel names for familiar objects while brain activity was monitored using fMRI. As training progressed, hippocampal response to the novel words decreased. This hippocampal disengagement was mirrored by increasing activity in the inferior parietal lobe as a function of training. The authors suggested that this is the neocortical site for permanent phonological storage of novel words. Hippocampal activity during training also correlated with behavioral measures of novel word knowledge. Participants who showed less decrease of hippocampal activity over the course of training had better learning

outcome at test, and improved more during training. Both the Davis et al. (2009) and the Breitenstein et al. (2005) studies suggest that the hippocampus is important in the initial encoding of novel words, but that other areas of the brain take over longer-term representation over the period of lexical consolidation, a prediction made by the CLS accounts of memory. I now turn to a more detailed description of the CLS accounts, which provide more information on the processes that are involved in consolidation, and make further predictions about its role in word learning.

Complementary Learning Systems

Lexical consolidation appears to allow the strengthening of newly learned lexical representations, and their integration with lexical–semantic networks of existing knowledge. The neuroimaging evidence shows that this change is associated with a shift from early hippocampal representation of new words to neocortical representation. These findings fit elegantly with predictions made by CLS accounts of memory (Alvarez and Squire, 1994; McClelland et al., 1995).

CLS models postulate two learning systems with different rates of learning, different structures of representation, and a transfer process between the two systems. The neocortex is responsible for permanent memory storage, and information here is represented in a form of overlapping representations. This overlap allows the information to be integrated with existing knowledge and generalization in learning to take place. However, there are several reasons why the learning rate needs to be slow in a system like this. McClelland et al. (1995) argued that slow learning, interleaved with reactivation of existing related memories, is necessary to ensure that the existing knowledge structure is not disturbed by the incoming information. This is a particularly important lesson from computational modeling, where massed learning of new information has been shown to lead to 'catastrophic interference,' where the new information can overwrite the old information. Alvarez and Squire (1994) further motivate a slow learning rate by pointing out that memories in the neocortex are represented over geographically disparate areas with slowly emerging connectivity. In these models, consolidation occurs in the form of gradual strengthening of the neocortical trace, during a reinstatement process where the memory trace is repeatedly reactivated over time. Reinstatement can occur with direct exposure to the stimulus, or with explicit recall of the stimulus. However, much of the time new memories are generated in response to events that occur only once, not providing the necessary reinstatement. Hence the CLS models argue that reinstatement takes place off-line as well, including during sleep.

Because the initial neocortical memory trace is too weak to activate fully on its own in the absence of external stimulation or in response to partial stimulation, a second system is needed to 'bind' the neocortical representation together until it has become strong enough through consolidation. The CLS models suggest that this system is provided by the medial temporal lobe, including the hippocampus. Unlike the neocortex, the hippocampus allows fast generation of sparse, non-overlapping representations. The sparseness of the hippocampal representations circumvents the catastrophic interference problem while allowing fast learning. Furthermore, since the connections between the hippocampus and neocortex can be modified quickly, the hippocampal and the emerging neocortical representations are linked immediately. This means that even partial activation of the emerging neocortical representation can be boosted with the support from the hippocampus to activate the complete representation. As the neocortical trace gains in strength with consolidation, the hippocampal support will eventually become superfluous, and the neocortical memory will become independent of the hippocampus.

Lexical Consolidation during Sleep

One of the predictions made by the CLS accounts is that much of memory consolidation should occur during sleep, as sleep provides an interference-free time for replay of newly acquired memories (Diekelmann and Born, 2010). Dumay and Gaskell (2007) asked whether lexical competition effects in novel words emerge after a consolidation opportunity consisting mostly of sleep or wake. Participants learned novel spoken words either in the evening (sleep group) or in the morning (wake group), and were tested immediately and after 12 h. Note that only the sleep group who learned the words in the evening got to sleep before the second test. The results showed that only the sleep group showed lexical competition effects after the 12 h, and that free recall performance also increased during sleep but not during wake. When the wake group was tested for a third time, after a night of sleep, their performance converged with that of the sleep group.

Recall that CLS accounts suggest that consolidation is driven by hippocampal replay of new memories, allowing their redistribution to neocortical stores. Tamminen et al. (2010) sought evidence of this in lexical consolidation during sleep. Participants learned novel spoken words in the evening and then spent the night in the laboratory under polysomnographic (PSG) monitoring. PSG allows the researcher to record the amount of time participants spend in different stages of sleep, as well as the identification of other sleep-related neural events. Lexical competition effects emerged during the night of sleep and were associated with sleep spindle activity. Sleep spindles are brief bursts of high frequency activation seen in nonrapid eye movement sleep. They are highly relevant to consolidation processes, as it has been suggested that they provide a marker of hippocampal–neocortical dialogue (Diekelmann and Born, 2010). This study provides evidence that the shift from hippocampal to neocortical representation of new words observed by Davis et al. (2009) occurs during sleep and is mediated by hippocampal reactivation, as predicted by CLS accounts.

Sleep-associated consolidation is relevant also for learning new words in a foreign language. Gais et al. (2006) asked English speaking participants to memorize English–German word pairs. Recall of the German words was tested immediately and again 24 or 36 h later. Half of the participants were trained in the evening, so they slept immediately after learning. The other half was trained in the morning, so training was followed by a normal day of wakefulness prior to a normal night of

sleep. Participants who slept shortly after training forgot significantly fewer German words than participants who were trained in the morning. In another experiment, half of the participants proceeded to have a normal night of sleep after learning, while the other half were sleep deprived for the duration of the night following learning. Recall test after a recovery night showed that the sleep group forgot significantly fewer words. These data show that sleep shortly after learning protected the new words from forgetting, possibly by rendering the new lexical representation more robust.

Lexical Consolidation during Wake

While sleep may provide the optimal brain state for memory consolidation, consolidation can also occur during wake (Mednick et al., 2011). Under the CLS view, consolidation during off-line states is needed due to the requirement of the slow-learning neocortex to have new information presented spread over time and interleaved with activation of existing related information. These conditions are needed to avoid disturbing existing knowledge. If learning during wake meets these conditions, then consolidation should occur even without sleep. Lindsay and Gaskell (2013) trained participants on novel spoken words either in one training session (massed learning) or in several sessions spread over the course of a day (spaced learning). In addition, the base words from which the novel words were derived from (e.g., *cathedral*, from which the novel word *cathedruke* was derived) were also presented over the course of the day so that novel word training was interleaved with activation of the relevant existing information. Lexical integration occurred by the end of the day (in both massed and spaced learning), but only if interleaving was allowed. If no interleaving was incorporated into the schedule, integration was found only after a night of sleep. These data support the assertion that one of the purposes of consolidation is to allow the integration of new information with existing information in an interleaved manner. Training that meets this requirement rarely occurs in real life, and therefore sleep may provide an off-line alternative.

Szmalec et al. (2012) have also argued that properties of the training regime determine whether sleep is necessary for lexical consolidation. They used the Hebb repetition paradigm to train participants on novel words that overlap with existing words. Here participants were visually presented with sequences of nine syllables for immediate serial recall, with one sequence repeated every third trial (i.e., the Hebb sequence). The Hebb sequence in this study consisted of three novel words. In the test phase, the integration of these novel words into the mental lexicon was tested using the pause detection and lexical decision tasks, following Gaskell and Dumay (2003). No evidence of lexical competition immediately after completion of the Hebb repetition task was found, but the effect emerged 12 h later, both when the 12 h consisted of sleep or wake. This again demonstrates the need for lexical consolidation to take place before lexical integration can be observed, but suggests that this consolidation can occur during wake. The authors argue that sleep is necessary only when the training results in weaker memory traces and when participants are explicitly asked to learn the new words. In the Hebb repetition paradigm participants were not explicitly aware that they would be tested on the novel words contained in the Hebb sequences, and the paradigm involved repeated testing during the training session, possibly resulting in a stronger memory trace for the novel words than in the phoneme monitoring task used in the studies that have reported effects of sleep on spoken novel word learning (Dumay and Gaskell, 2007; Tamminen et al., 2010).

Lexical Consolidation in Children

Most of the studies demonstrating lexical consolidation have been carried out on adults. What role, if any, does lexical consolidation play in young children? It is well known that children as young as 2-years-old are able to learn new words remarkably quickly as a result of minimal exposure to the word and its meaning. This phenomenon of 'fast-mapping' (Carey and Bartlett, 1978) suggests that perhaps the need for consolidation seen in adults is less prominent in children. To explore this issue, Henderson et al. (2012) trained 7–12 year olds novel spoken words and tested lexical competition effects immediately and after a consolidation opportunity consisting of sleep or wake, following the design of Dumay and Gaskell (2007). Just like adults, the children showed no evidence of newly learned words engaging in lexical competition immediately after training. The effect emerged after 12 h, but only in the group that slept during that time. A two-alternative forced choice recognition memory task and a cued recall task also showed improvements in performance that were specific to sleep, as reported in adults (Tamminen et al., 2010). Converging data were reported by Brown et al. (2012) who found that in 7- and 12-year-olds cued recall of newly learned words is improved over a 24-h period following learning (and including nocturnal sleep), but not over a short period of 3–4 h that also did not include sleep. Together these data suggest that word learning in children is not complete immediately after exposure, and that lexical consolidation operates in children much like it does in adults. Furthermore, sleep appears to be the optimal brain state for lexical consolidation to occur for children as well as adults.

Conclusions

The evidence described here suggests that lexical consolidation operates on several levels. At one level, consolidation facilitates access to novel word representations as seen in gradually improving performance in recognition and recall tasks. At another level, consolidation is necessary for integrating novel lexical representations with different levels of linguistic knowledge, ranging from low level phonological knowledge to lexical and semantic knowledge. Sleep appears to be the optimal state for this lexical consolidation to occur, and this is likely to be due to hippocampal–neocortical interaction taking place during sleep. Neuroimaging evidence supports this view by implicating the hippocampus in the early stages of word learning prior to consolidation, while neocortical areas seem to mediate representation of consolidated novel words. These

findings are consistent with CLS accounts of memory, and seem to apply both to adult and child populations.

While this article has focused on the consolidation of new lexical representations, it is worth noting in closing that new research has begun to identify other aspects of language learning that require memory consolidation. For example, Tamminen et al. (2012) trained participants on new affixes (e.g., *-nule*) attached to familiar word stems (e.g., *sleepnule*). Participants showed evidence of having learned the new affix immediately after training when it was attached to the same stem as during training, but such evidence was seen only after consolidation if the affix was attached to a stem not seen during training (e.g., *jugnule*), suggesting that newly learned affixes become context-independent only after consolidation. Similar evidence of linguistic generalization was shown by Gomez et al. (2006) who exposed infants to an artificial language governed by a syntactic rule. Only infants who took a nap after exposure were able to apply the rule to new words, suggesting that sleep-associated consolidation is critical in generalization. These and the examples described earlier demonstrate how language learning provides a uniquely rich environment for uncovering the mechanisms underlying memory consolidation. Our understanding of both domains will benefit as interest in this work continues to grow.

Lexical Processes (Word Knowledge): Psychological, Computational and Neural Aspects

Matthew A Lambon Ralph, School of Psychological Sciences, University of Manchester, Manchester, UK

Abstract

This entry reviews the psychological and neural aspects of the mental lexicon and word knowledge. This topic is covered in six main sections. The first summarizes the various empirical techniques – experimental psychology, neuropsychology, transcranial magnetic stimulation, functional imaging, and computational modeling – which are used to investigate word knowledge and how that is represented in the brain. This is followed by a description of the traditional conception of the lexicon including an overview of Morton's influential logogen theory. The third section summarizes the data, which have been used to argue that word knowledge is supported by a number of interactive yet functionally distinct lexicons. These traditional views of the mental lexicon are contrasted in the fourth section with a different approach that has arisen from a form of computational models (e.g., the Seidenberg and McClelland word reading and recognition model), which are able to extract word knowledge without having a 'lexicon.' The penultimate section reviews how lexical knowledge interacts with the remaining language system to give rise to specific language activities such as speech production, reading aloud, and verb inflection. The final section considers how future work may ultimately inform us about the neural basis of word knowledge.

> He doth not neglect the profit of Lexicons (wherein all sayings and speeches are numbered)
>
> E. Topsell, The historie of foure-footed beastes, 1607.

If one looks in any psychology or psycholinguistics textbook for a definition of the mental *lexicon*, the superficial description given does not differ to one of the first uses of the word quoted above from the Oxford English Dictionary. Most modern researchers would agree that the 'lexicon' refers to our knowledge of the words in our vocabulary. There is, however, a very broad range of opinion if one asks the next obvious questions: what is this knowledge and how is it represented in the brain?

As with many areas of higher brain function, studies of the mental lexicon generally follow one of two levels of explanation: descriptive and computational. There are currently no theories of word knowledge at the level of individual neurons. Descriptive explanations try to outline the nature of the lexicon in detail, attempting to establish both what information is represented by the lexicon and how this information is accessed. Computational explanations provide more explicit descriptions of word knowledge and lexical processes either through formal mathematical treatments or in the form of computer-based models that take a specific input and transform it to the appropriate output.

Studies on the lexicon can be grouped into four categories, each employing a number of different research methodologies:

1. *Neurologically intact participants*: This type of research relies principally on reaction time and to a lesser extent on accuracy, as the critical dependent measures. Participants are typically required to give some form of response to spoken or written words (word recognition) or to give a spoken, single name (word production). A large number of different tasks are employed in each of these modalities. These include lexical decision (deciding whether a spoken or written stimulus is a real word or not), word monitoring (listening to spoken input and indicating when a target word has been presented), and picture naming and word naming (single word reading aloud). All these techniques aim to capture variations in reaction times in terms of differences between words of different types and/or words with different psycholinguistic characteristics. Alternatively, the experimenter aims to manipulate a baseline reaction time through different presentation conditions (for example, the experimenter may investigate the effect of semantic priming – presenting a target word soon after a semantically related item).
2. *Permanent or transient brain dysfunction*: The critical assumption underpinning neuropsychological research is that different aspects of language or, in this case, word knowledge are supported by different areas of the brain (concentrated almost entirely within the left, dominant hemisphere). Therefore, by studying patients with damage to one of these areas, it should be possible to reveal the underlying characteristics of how the human brain supports language, including word knowledge. Unlike studies with neurologically intact participants, most neuropsychological research relies on accuracy rather than reaction time measures. Studies are conducted on groups of patients (comparing them to control participants and/or different types of patient) or individual cases (Shallice, 1988). A number of recent studies have also used a technique known as case-series methodology in which patients are selected on the basis of having the same type of deficit but at different levels of severity (Schwartz and Dell, 2011). More recently, transcranial magnetic stimulation (TMS) has been used to test the effects of transient, localized cortical dysfunction on task performance in neurologically intact participants. The technique uses an electromagnetic field to stimulate the cortex underlying the coil, and the effect on task performance is measured (Walsh and Cowey, 2000). With the correct design of coil (e.g., a figure-of-eight), it is possible to apply a focused magnetic field and thus influence a targeted, small cortical region. As a consequence, it is possible to investigate the role of target areas and also the timecourse of

their function. The method is, therefore, a complement to neuropsychological studies and provides a mechanism by which the functional relevance of regions identified by functional neuroimaging can be assessed.

3. *Functional neuroimaging*: For those techniques that concentrate more on spatial than temporal resolution, the underlying assumption for functional neuroimaging is the same as for neuropsychological studies with aphasic patients. In this way, functional magnetic resonance imaging (fMRI) or positron emission tomography (PET) compare words that vary according to a specific characteristic either using a parametric, subtraction methodology (looking for areas of the brain that are more active for one set than another) or a correlational technique (looking for areas in the brain where changes in activation are correlated with a changing characteristic of the presented words). Other imaging techniques are able to investigate how the timecourse of activation compares for words of different type. Such methods include event-related potentials and magnetoencephalography.
4. *Computational modeling*: This is a formal technique designed to instantiate a proposed computational description of the processes underlying a specific set of behaviors. Most computational models do this by specifying an arrangement of simple processing units (known as a *network architecture*). The architecture describes how simulated activation can potentially be passed between these units. Information is represented either in localist form (the activation of a single unit corresponds to a specific piece of information – e.g., a word) or in a distributed manner (a number of pieces of information are represented by different patterns of activation across the same set of units; therefore, the activation of a particular unit is not unique to a specific datum). These computational models also differ along another dimension. In some models, the strength of the connection between units (that governs how much activation is passed between them) is specified explicitly by the modeler. Other networks use mathematical algorithms such that the model can extract its own set of weights to performance optimally. In doing so, these latter types of network can also be used to compare patterns of development as well as mature performance between the model and human subjects. Both types of model can be used to simulate disordered behavior (e.g., through brain injury) by various means including the removal of units and/or their connections, or by adding noise to the activation of units.

These four methods have given rise to a vast literature on the nature of the lexicon and its interaction with the rest of the language system. Some of the major themes arising from this work are summarized below.

The Traditional Conception of a Lexicon

Many theories of lexical representation are not that different from Topsell's definition from 1607: the lexicon is a list of all the words in a person's vocabulary. By some form of 'lookup' function, all or part (in the case of models with multiple lexicons, see below) of our knowledge about a word is retrieved. An early functional and mathematical description of this process was given by Morton with his influential logogen theory (1969), which was originally applied to explain word recognition but was extended later to address spoken and written recognition and production. The key elements to this approach are as follows. Each word is represented by a separate unit, or logogen, which gathers evidence for the presence of that word in the input (in the form of sensory input for recognition or semantic memory for production). Each logogen does this relatively independently of the others. A word is recognized or produced when there is sufficient positive evidence for that word in the input (e.g., the letters in the written input match those for the target word). At this point, the logogen makes other information about that word available – such as the word's meaning or its pronunciation. With reference to signal detection theory, Morton also included the notion of a 'threshold,' which governs how much positive evidence is required before the logogen makes a response. In this way, word frequency effects in recognition and production are described in terms of different thresholds for different logogens (high-frequency words have lower thresholds and thus require less positive evidence to respond).

How Many Lexicons Are There?

If one considers the literate adult, the sum total of the acquired knowledge can be classified into three forms: the meaning of words; the sound of each word; and the written form or orthography. With reference to the traditional view of the lexicon (see above), some researchers have argued that these three forms of information are represented in separate lexicons: lexical semantics, a speech lexicon, and an orthographic lexicon. Although most models have interconnections between these different lexicons (at some level they need to combine information to reflect all aspects of word knowledge), the notion is that they are discrete entities at both a functional and a neural level. Functionally, each lexicon can then have its own dedicated form of representation and associated processes. At the neural level (for both neuropsychological and neuroimaging studies) this means there are distinct regions in the brain that can be damaged/activated relatively independently of each other. The cognitive neuropsychology literature, in particular, has also encouraged a further division in the mental lexicon – for input and output processes. The notion here is that there might be four separate lexicons to cover the four combinations of recognition and production for spoken and written words (for an overview, see Ellis and Young, 1988). The same division is not proposed for meaning, which in a sense would be nonsensical anyway (for effective communication, the meaning driving the speaker/writer's output must be the same as that decoded by the listener/reader). The need to have separate input and output representations is still contested, however. Some neuropsychological data would seem to favor this position – for example, there are patients with word-finding difficulties (anomia) who do not have trouble understanding words (word deafness), and other patients with the opposite pattern. However, more studies are needed to rule out the possibility that the patterns reflect modality-specific nonlexical deficits or the fact that expression is always more vulnerable to impairment than receptive abilities.

Two separate strands of research have argued for another lexicon – the semantic lexicon or lemmas, which mediate between meaning and other language processes and representations (neuropsychology – e.g., Butterworth et al., 1984; speech production – e.g., Levelt, 1992). In speech production, Levelt (1992) has argued for a two-stage process within lexical access. First, the meaning of the intended utterance is used to select a single abstract lexical form, a lemma (that also codes for syntactical markings such as gender and number), and then this in turn activates a lexeme, which makes the sound of the word available in terms of the constituent phonemes, their arrangement, and associated stress pattern. There is, however, a general concern with this direction of theorizing in that a proliferation of multiple lexicons means the potential for redundancy of representations is much higher, and tends to make the theories unfalsifiable.

An Alternative Conception of the Nature of Lexical Knowledge?

A quite different approach has been adopted by some parallel distributed processing (PDP) computational models in which there is knowledge of the words in our vocabulary but not a lexicon – at least, in the traditional sense of that word. A landmark publication in this respect was the word reading and recognition model of Seidenberg and McClelland (1989). In this framework word knowledge is represented as distributed patterns of activation across three 'primary' systems corresponding to orthography, phonology, and semantic memory. Through a gradual learning process, in which the weights of the connections within and between these representational layers are adjusted, models of this type extract word 'knowledge' from the vocabulary they are trained on. Note that this is quite different from the traditional metaphor of looking up an entry in the dictionary or Morton's logogen theory. The Seidenberg and McClelland model does not have a list of all the known words (i.e., a lexicon) so the terms 'access' and 'retrieval' are redundant. Instead the model takes one form of input (e.g., the written word) and then computes the appropriate representation reflecting the meaning and/or the pronunciation. In this way the model can be said to have word knowledge but not a lexicon. This is further reinforced by the fact that the model processes novel words (nonwords that, by definition, cannot be in a lexicon) through the very same set of units corresponding to the written or spoken form. Another potential allure of this approach to word knowledge is that the formulation may help when future research (see below) attempts to bridge the gap between brain and behavior. The neural basis for the primary systems of semantics, phonology, and orthography is also much more obvious. It is possible, for example, that orthography reflects a stable set of representations extracted through visual perception (Behrmann et al., 1998), phonology arises from the interplay of auditory and motor interactions (Plaut and Kello, 1999), and semantic memory, or conceptual knowledge, reflects high-level abstraction based on all forms of verbal and nonverbal experience, perhaps supported primarily by regions within the temporal lobes (Lambon Ralph et al., 2010; Patterson et al., 2007).

This alternative approach has also been used to address some of the data that have led researchers, using a traditional view of the lexicon, to posit the need for multiple lexicons (see above). For example, patients with both poor comprehension and production of words (whether spoken or written) are described from a traditional viewpoint in terms of damage to a semantic lexicon that mediates between conceptual knowledge and the language system (Butterworth et al., 1984). The same data are adequately captured by PDP computational principles in terms of the nature of the mapping between representations for words vs pictures/objects (Lambon Ralph et al., 2001; Rogers et al., 2004). The fact that there is an arbitrary mapping between phonology/orthography and conceptual knowledge, unlike the mapping for pictures or objects, means that verbal comprehension and production are highly vulnerable to damage to the system that represents the meaning of both words and pictures.

How Does Word Knowledge Give Rise to Specific Language Activities?

Within the repertoire of language activities, there are some that are assumed to depend directly on word knowledge or lexical information. For example, understanding words or producing words is assumed to proceed with reference to lexical information. So, as described above, within a logogen framework speech production occurs by the target meaning acting as an input to a set of logogens, which selects the correct word and then makes the spoken form available. There is also a direct use of word knowledge in PDP computational models as well – the knowledge extracted through learning the mapping between semantics and phonology is used to produce the correct spoken form in speech production. Other language activities are assumed to depend upon a combination of lexical knowledge and other nonlexical processes. So, for example, Levelt (1992) proposes that speech production is based upon a 'formulator' that specifies the syntactical frame for a sentence into which lexical representations (lemmas) and their associated knowledge are fitted. Two other well-known examples are reading aloud and the past tense transformation of English verbs. Researchers studying the process of reading aloud have classified words into three basic types: (1) most words, known as regular or consistent words, are pronounced in line with their spellings (examples of these are YARD and MINT); (2) a smaller but still substantial number of irregular or inconsistent words deviate from the typical spelling-to-sound translations (examples of these are YACHT and PINT); (3) we are also able to read new or novel words without extra training (e.g., EMAIL or WUG). There is a very similar classification for describing the past tense of an English verb. (1) There are many regular verbs, all of which are turned into the past tense by the addition of -ED (e.g., *talk* → *talked* or *need* → *needed*), and a smaller number of irregular verbs which mark the past tense in another way (e.g., *speak* → *spoke* or *think* → *thought*). We are also able to produce the past tense for new or novel verbs (e.g., *email* → *emailed*, *wug* → *wugged*), again without any specific training on these novel forms. The traditional theories of verb inflection (the dual-mechanism account – Pinker, 1999) and reading aloud (the dual-route theory – Coltheart et al., 2001) have both used this tripartite division of word type to argue that each language activity is underpinned by two distinctly different processes. The two theories are sufficiently similar that they can

be summarized together. Irregular words/verbs (e.g., PINT → 'pint' for reading aloud and 'ring' → 'brought' for verb tense) are said to be translated by reference to a lexicon – or indeed, in the case of reading, two lexicons: one orthographic and the other phonological – that stores the whole specific word form for every irregular item in the language. The ability to read or inflect novel forms is explained in these theories by positing a task-specific, generative process encapsulated by a set of rules: three rules for the three allomorphs required for the inflection of regular verbs (/t/,/d/,/@d/) and an extensive series of rules for the translation of letters/graphemes into phonemes. Neuropsychological investigations of impairments to both reading aloud and past tense production have highlighted two contrasting patterns that have been taken to support these dual-mechanism theories (some patients have specific difficulties with irregular forms and others with novel forms: see Ullman et al. (1997) for verb morphology; an overview of acquired dyslexia can be found in Ellis and Young (1988)).

Again, PDP computational models have taken a different approach (verb morphology (Joanisse and Seidenberg, 1999); reading aloud (Plaut et al., 1996)). In these frameworks word knowledge is not reflected in a lexicon and thus the strict division between the lexicon and the generative rules does not apply. Instead the interaction between and within the primary systems (semantics, phonology, and orthography) not only gives rise to word knowledge, the models are also capable of transforming one form of representation into another (e.g., reading is orthography → phonology) for all three word types (irregular, regular, and novel). Critically, however, the division of labor among the primary representations is not constant for the different word types, and dissociations in performance can occur if one of the primary systems is damaged (for an overview of this perspective on acquired dyslexias, see Patterson and Lambon Ralph, 1999). This overarching hypothesis has been tested and explored in both neuropsychological and TMS investigations. The core, central role of semantic information in supporting a range of verbal and nonverbal activities has been demonstrated through detailed investigations of patients with semantic dementia who have a selective yet progressive degradation of multimodal conceptual knowledge as a result of atrophy focused on the ventrolateral anterior temporal lobes (Patterson et al., 2006). These studies are important because they show that the same, singular semantic deficit leads to impaired performance across a range of diverse language activities (including surface dyslexia, poor past tense production of irregular verbs, surface dysgraphia, pronounced anomia, etc.). Under the more traditional lexicon-based accounts, this set of co-occurring deficits would require the unlikely situation of simultaneous yet selective impairments of the lexical representations in all domains. The importance of semantic representations in supporting 'lexical knowledge' has also been demonstrated in neurologically intact participants following TMS of the lateral anterior temporal lobe (a region that exhibits significant atrophy in semantic dementia patients (Holland and Lambon Ralph, 2010; Pobric et al., 2007)).

Beyond semantic representations, some studies have also explored the important role that phonological and visual 'primary' systems play in verbal activities. These include demonstrations that generalized phonological impairments lead to a specific form of acquired dyslexia and dysgraphia in which performance is more accurate for words than nonwords (Crisp and Lambon Ralph, 2006; Patterson and Marcel, 1992; Rapcsak et al., 2009). Likewise, some researchers have argued that pure alexia (a selective disorder of word recognition that spares spelling – 'alexia without agraphia) is caused by a more general visual impairment (Behrmann et al., 1998; Woodhead et al., 2011).

Future Directions

Research on the psychological aspects of word knowledge will, no doubt, continue in the future. One potential area for additional research must be on the neural aspects of word knowledge. Clues about the neural basis of word knowledge can be gleaned, in part, from relating the neuropsychological impairments of patients back to the underlying distribution of brain damage. In addition, functional neuroimaging can be used to explore which brain areas become more active when word knowledge is required. Interestingly, although some well-known early functional neuroimaging studies searched for the neural bases of spoken and written lexicons (Howard et al., 1992), most contemporary investigations are focused on specific language activities (for an excellent and thorough review of the development of language-related functional neuroimaging and its findings, see Price, 2012). Likewise, there is potential to use TMS to explore the necessity of specific brain regions in various aspects of word knowledge. While there have been various explorations of semantics and phonology using TMS (e.g., Devlin et al., 2003; Hartwigsen et al., 2010; Pobric et al., 2007), this line of research is still in its infancy and it has the potential to reveal much finer aspects of word knowledge and its neural representation. Finally, it should be noted that even if we have a range of techniques to explore the behavioral and neural correlates of word knowledge, we will still need formal methods for exploring how behavior arises from these neural mechanisms – i.e., to bridge between brain and mind. Indeed, functional neuroimaging has already demonstrated that many language activities are not supported by a single brain region but rather by a network of brain areas (Price, 2012). Clearly then, there is a need to understand not only the neurocomputation occurring in each region but also their connectivity and network-based activity. One possibility in this domain is for computational models of language to embrace increasing amounts of neuroanatomy by utilizing this information to constrain the architecture of the models. Although only few in number, the handful of implemented models that have taken this approach show great promise to provide a formal bridge between the neural and cognitive aspects of word knowledge (Lambon Ralph et al., 2001; Plaut, 2002; Ueno et al., 2011).

Lexical Semantics

Dirk Geeraerts, Faculty of Arts, KU Leuven, Leuven, Belgium

This article is a revision of the previous edition article by D.A. Cruse, volume 13, pp. 8758–8764, © 2001, Elsevier Ltd.

Abstract

The scope of linguistic lexical semantics is described from a theoretical and descriptive point of view: an overview of the main theoretical approaches that have succeeded each other in the history of lexical semantics (prestructuralist historical semantics, structuralist semantics, cognitive semantics) provides a framework for illustrating the various descriptive topics and models that were introduced by the successive theories.

Lexical semantics is the study of word meaning. To get a good idea of the scope of lexical semantics (and the present article), a number of demarcational distinctions need to be introduced. First, linguistic semantics is obviously not restricted to lexical semantics: for a broader view of meaning in language, including the crucial areas of grammatical and discursive semantics, see the article Semantics. Second, although the label 'lexical semantics' may suggest otherwise, morphological semantics (the study of the meaning of morphemes and the way in which they combine into words) is usually considered a separate field from lexical semantics proper. Morphological semantics is not covered by the present article. Third, the study of the meaning of words does not exhaust the linguistic study of words: topics like lexical variation across language varieties, borrowing, phraseology, or the origin of words are distinct from the study of word meaning, but like lexical semantics, they form part of the broader field of lexicology. Again, lexicology at large (and lexicography, as an applied discipline) lies beyond the scope of the present chapter; see the article 53059 for more.

The article is organized in a historical rather than thematic way, because the various topics treated in lexical semantics are very much tied up with the different theoretical approaches that have dominated the development of lexical semantics. For an entry-level text on lexical semantics, see Murphy (2010) or the chapters devoted to word meaning in Saeed (2009), Riemer (2010), and Cruse (2010). For a more extensive and detailed overview of the main historical and contemporary trends of research in lexical semantics, see Geeraerts (2010).

Prestructuralist Historical Semantics

The prestructuralist period (ranging from the middle of the nineteenth century up to the 1930s) was the heyday of historical semantics, in the sense that the study of meaning change reigned supreme within semantics. The main theoretical achievement of prestructuralist historical semantics consists of various classifications of types of semantic change, coupled with considerable attention for psychological processes as the explanatory background of changes: the general mechanisms of change included in the classifications were generally considered to be based on the associative patterns of thought of the human mind. Important figures are Paul (1920) (first edition 1880), Bréal (1897), and Stern (1931).

The most common classification of semantic changes emerging from this tradition includes four basic types: specialization, generalization, metaphor, and metonymy. In the case of semantic *specialization*, the new meaning is a restriction of the old meaning: the new meaning is a subcase of the old. In the case of semantic *generalization*, the reverse holds: the old meaning is a subcase of the new. Classical examples of specialization are *corn* (originally a cover term for all kinds of grain, now specialized to 'wheat' in England, to 'oats' in Scotland, and to 'maize' in the United States), *starve* (moving from 'to die' to 'to die of hunger'), and *queen* (originally 'wife, woman,' now restricted to 'king's wife, or female sovereign'). Examples of generalization are *moon* (primarily the earth's satellite, but extended to any planet's satellite) and French *arriver* (which originally meant 'to reach the river's shore, to embank,' but which now signifies 'to reach a destination' in general). There is a lot of terminological variation in connection with specialization and generalization. 'Restriction' and 'narrowing' of meaning equal 'specialization,' while 'extension,' 'schematization,' and 'broadening' of meaning equal 'generalization.' Also, the meanings involved can be said to entertain relations of taxonomical subordination or superordination: in a taxonomy (a treelike hierarchical classification) of concepts, the specialized meaning is subordinate with regard to the original one, whereas the generalized meaning is superordinate with regard to the original.

Like specialization and generalization, it is convenient and customary to introduce metaphor and metonymy together, even though the relationship is not as close as with the former pair. *Metaphor* is then said to be based on a relationship of similarity between the old and the new reading, and *metonymy* on a relationship of contiguity. Current computer terminology yields examples of both types. The desktop of your computer screen, for instance, is not the same as the desktop of your office desk – except that in both cases, it is the space (a literal space in one case, a virtual one in the other) where you position a number of items that you regularly use or that urgently need attention. The computer desktop, in other words, is not literally a desktop in the original sense, but it has a functional similarity with the original: the computer reading is a metaphorical extension of the original office furniture reading. Functional similarities also underlie metaphorical expressions like *bookmark*,

clipboard, *file*, *folder*, *cut*, and *paste*. *Mouse*, on the other hand, is also metaphorically motivated, but here the metaphorical similarity involves shape rather than function. But now consider a statement to the effect that your desktop will keep you busy for the next 2 weeks, or that you ask aloud where your mouse has gone when you are trying to locate the pointer on the screen. In such cases, *desktop* and *mouse* are used metonymically. In the former case, it's not the virtual space as such that is relevant, but the items that are stored there. In the latter case, it's not the mouse as such (the thing that you hold in your hand) that you refer to, but the pointer on the screen that is operated by the mouse. The desktop and the stored items, or the mouse and the pointer, have a relationship of real-world connectedness that is usually captured by the notion 'contiguity.' When, for instance, one drinks a whole bottle, it is not the bottle but merely its contents that are consumed: *bottle* can be used to refer to a certain type of container, and the (spatially contiguous) contents of that container. When lexical semanticians state that metonymical changes are based on contiguity, contiguity should not be understood in a narrow sense as referring to spatial proximity only, but more broadly as a general term for various associations in the spatial, temporal, or causal domain.

With the shift toward a structuralist approach that occurred around 1930, lexical semantics switched from a preference for diachronic studies to a preference for synchronic studies. However, the poststructuralist cognitive approach (see the Section Cognitive Semantics below) provides a new impetus for historical lexical semantics (see, e.g., Geeraerts, 1997; Winters et al., 2010).

Structuralist Semantics

Inspired by the Saussurean conception of language, structural semantics originated as a reaction against prestructural historical semantics. The origins of structural semantics are customarily attributed to Trier (1931), but while Trier's monograph may indeed be the first major descriptive work in structural semantics, the first theoretical and methodological definition of the new approach is to be found in Weisgerber (1927), a polemical article that criticized historical linguistics on three points. First and foremost, because the vocabulary of a language is not simply an unstructured set of separate items, and because the meaning of a linguistic sign is determined by its position in the linguistic structures in which it takes part, the proper subject matter of semantics is not the atomistic changes of word meanings that historical semantics concentrated on, but the semantic structure of the language that demarcates the meanings of individual words with regard to each other. Second, because that structure is a linguistic rather than a psychological phenomenon, linguistic meanings should not be studied from a psychological perspective, but from a purely linguistic one. And third, because semantic change has to be redefined as change in semantic structures, synchronic semantics methodologically precedes diachronic semantics: the synchronic structures have to be studied before their changes can be considered. The realization of this attempt to develop a synchronic, nonpsychological, structural theory of semantics depends on the way in which the notion of semantic structure is conceived. In actual practice, there are mainly three distinct definitions of semantic structure that have been employed by structuralist semanticians. More particularly, three distinct kinds of structural relations among lexical items have been singled out as the proper methodological basis of lexical semantics. First, there is the relationship of semantic similarity that lies at the basis of semantic field analysis and componential analysis. Second, there are unanalyzed lexical relations such as synonymy, antonymy, and hyponymy. Third, syntagmatic lexical relations lie at the basis of a distributional approach to semantics.

Lexical Fields and Componential Analysis

A lexical field is a set of semantically related lexical items whose meanings are mutually interdependent. The single most influential study in the history of lexical field theory is Trier's (1931) monograph, in which he presents a theoretical formulation of the field approach and investigates how the terminology for mental properties evolves from Old High German up to the beginning of the thirteenth century. Theoretically, Trier emphasizes the structuralist insight that only a mutual demarcation of the words under consideration can provide a decisive answer regarding their exact value. Words should not be considered in isolation, but in their relationship to semantically related words: demarcation is always a demarcation relative to other words. Trier illustrates the idea with the image of a mosaic: the substance of human knowledge, the contents of cognition is divided by language into a number of adjoining small areas, in the way in which a mosaic divides two-dimensional space by means of contiguous mosaic stones.

While different conceptions of the notion 'lexical field' were suggested after Trier's initial formulation, the most important development is the emergence of componential analysis as a technique for formalizing the semantic relationships between the items in a field: once you have demarcated a lexical field, the internal relations within the field will have to be described in more detail. It is not sufficient to say that the items in the field are in mutual opposition – these oppositions will have to be identified and defined. Componential analysis is a method for describing such oppositions that takes its inspiration from structuralist phonology: just like phonemes are described structurally by their position on a set of contrastive dimensions, words may be characterized on the basis of the dimensions that structure a lexical field. Componential analysis provides a descriptive model for semantic content, based on the assumption that meanings can be described on the basis of a restricted set of conceptual building blocks – the semantic 'components' or 'features.' Componential analysis was developed in the second half of the 1950s and the beginning of the 1960s by European as well as American linguists, largely independently of each other. Its major impact would come from its incorporation into generative grammar: the publication of Katz and Fodor (1963) marked a theoretical migration of lexical semantics from a structuralist to a generativist framework. (This is a line of development that we will not pursue here, however, because it leads away from lexical semantics to grammatical and formal semantics.)

For a brief illustration of the principles of componential analysis, we may refer to the work of Pottier. Pottier (1964) provides an example of a componential semantic analysis in his description of a field consisting, among others, of the terms

siège, *pouf*, *tabouret*, *chaise*, *fauteuil*, and *canapé* (a subfield of the field of furniture terms in French). The word which acts as a superordinate to the field under consideration is *siège*, 'seating equipment with legs.' If we use the dimensions s1 'for seating,' s2 'for one person,' s3 'with legs,' s4 'with back,' s5 'with armrests,' s6 'of rigid material,' then *chaise* 'chair' can be componentially defined as (+s1, +s2, +s3, +s4, −s5, +s6), and *canapé* 'sofa' as (+s1, −s2, +s3, +s4, +s5, +s6), and so on.

Relational Semantics

Like componential analysis, relational semantics as introduced by Lyons (1963) develops the idea of describing the structural relations among related words, but restricts the theoretical vocabulary that may be used in such a description. In a componential analysis, there is no restriction on the features that enter into the description, and as in Pottier's example, these features are often of a 'real world' kind: they name properties of the things referred to rather than properties of the meanings as such. But structuralism is interested in the structure of the language rather than the structure of the world, and so it may want to use a different type of descriptive apparatus, one that is more purely linguistic. Relational semantics looks for such an apparatus in the form of sense relations like synonymy (identity of meaning) and antonymy (oppositeness of meaning): the fact that *aunt* and *uncle* refer to the same genealogical generation is a fact about the world, but the fact that *black* and *white* are opposites is a fact about words and language. Instead of deriving statements about the synonymy or antonymy of a word (and, in general, statements about the meaning relations it entertains) from a separate and independent description of the word's meaning, the meaning of the word could be defined as the total set of meaning relations in which it participates. A traditional (or perhaps naive) conception of synonymy would for instance describe the meaning of both *quickly* and *speedily* as 'in a fast way, not taking up much time,' and then conclude to the synonymy of both terms on the basis of the identity in their content description. Lyons by contrast deliberately eschews such content descriptions, and equates the meaning of a word like *quickly* with the synonymy relation it has with *speedily*, plus any other relations of that kind.

In the actual practice of relational semantics, 'relations of that kind' specifically include – next to synonymy and antonymy – relations of hyponymy (or subordination) and hyperonymy (or superordination), which are both based on taxonomical inclusion. The major research line in relational semantics involves the refinement and extension of this initial set of relations. The most prominent contribution to this endeavor after Lyons is found in Cruse (1986). Murphy (2003) is a thoroughly documented critical overview of the relational research tradition.

Distributional Semantics

Lexical fields as originally conceived are based on paradigmatic relations of similarity. One extension of the field approach, then, consists of taking a syntagmatic point of view. There are in fact two ways in which a syntagmatic analysis was suggested to be relevant for structuralist semantics. First, words may have specific combinatorial features which it would be natural to include in a field analysis. A verb like *to comb*, for instance, selects direct objects that refer to hair, or hairlike things, or objects covered with hair. Describing that selectional preference should be part of the semantic description of *to comb*. For a considerable period in the development of structural linguistics, these syntagmatic affinities received less attention than the paradigmatic relations, but in the 1950s and 1960s, the concept surfaced under different names in structuralist and generativist semantics. Firth (1957) for instance introduced the (now widely used) term *collocation*.

The second way in which the syntagmatics of lexical items could play a role in lexical field analysis is more radical than the mere incorporation of lexical combinatorics into the notion of lexical field: if the environments in which a word occurs could be used to establish its meaning, structuralist semantics could receive a firm methodological basis. The general approach of a distributionalist method is summarized by Firth's dictum: "You shall know a word by the company it keeps." A similar assumption is expressed by the 'distributional hypothesis' as formulated by Harris (1954): words that occur in the same contexts tend to have similar meanings. In the final decades of the twentieth century, major advances in the distributional approach to semantics were achieved by applying a distributional way of meaning analysis to large text corpora. Sinclair, a pioneer of the approach, developed his ideas (see Sinclair, 1991) through his work on the *Collins Cobuild English Language Dictionary*, for which a 20 million word corpus of contemporary English was compiled.

The distributional analysis in the corpus-based approach is not restricted to constituents and syntactic classes, but it takes into account the actual words in the context of which the target word appears. Firth remarked that part of the 'meaning' of *cows* can be indicated by such collocations as *They are milking the cows*, *Cows give milk*. This observation is taken as a methodological starting point: the words co-occurring with another one help to identify the properties of the word under scrutiny. An example (taken from Stubbs, 2002) may illustrate the basic idea. A classic example of homonymy in English is the item *bank*, which is either a financial institution or an area of sloping ground, specifically the raised ground on the side of the river or underneath a shallow layer of water. The sets of words that these two exemplars of *bank* normally occur with hardly overlap. Looking at compounds on the one hand, and on the other hand at co-occurring items within a few words to the left or right of *bank*, Stubbs comes up with the following lists:

bank account, bank balance, bank robbery, piggybank cashier, deposit, financial, money, overdraft, pay, steal

sand bank, canal bank, river bank, the South Bank, the Left Bank, Dogger bank, Rockall Bank, Icelandic Banks cave, cod, fish, float, headland, sailing, sea, water

The entities in the environment of the two homonyms appear to differentiate efficiently and effectively between the two meanings, and in that sense, a systematic analysis of the co-occurring items would appear to be an excellent methodological ground for lexical-semantic analysis.

In Sinclair's original conception, a collocational analysis is basically a heuristic device to support the lexicographer's

manual work. A further step in the development of the distributional approach was taken through the application of statistics, as when Church and Hanks (1990), working in the context of Sinclair's CoBuild project, introduced the Pointwise Mutual Information index as a statistical method for establishing the relevance of a collocation. Once a statistical measure of association of this kind was introduced, further possibilities opened up for quantifying the distributional approach; for instance, a whole variety of association measures has been suggested and researched. Also, the statistical turn in thinking about contextual distributions allowed for a rapprochement with the field of information retrieval and Natural Language Processing where so-called *word space models* constitute an advanced form of distributional corpus analysis, applied to problems like word sense disambiguation and synonym extraction (see Agirre and Edmonds, 2006). In this methodological form, the theoretical link between the distributional approach and structuralist semantics has all but disappeared: the method is very much a theoretically neutral one.

Cognitive Semantics

Compared to prestructuralist semantics, structuralism constitutes a move toward a more purely linguistic type of lexical semantics, focusing on the linguistic system rather than the psychological background or the contextual flexibility of meaning. With the poststructuralist emergence of cognitive semantics, the pendulum swings back to a position in which the distinction between semantics and pragmatics is not a major issue, in which language is seen in the context of cognition at large, and in which language use is as much a focus of enquiry as the language system. Cognitive semantics emerged in the 1980s as part of cognitive linguistics, a loosely structured theoretical movement that opposed the autonomy of grammar and the marginal position of semantics in the generativist theory of language. Important contributions to lexical semantics include prototype theory, conceptual metaphor theory, frame semantics, and the emergence of usage-based onomasiology.

Prototype Effects and Radial Sets

The prototype-based conception of categorization originated in the mid-1970s with Rosch's psycholinguistic research into the internal structure of categories. Rosch concluded that the tendency to define categories in a rigid way clashes with the actual psychological situation. Linguistic categories do not have sharply delimited borderlines. Instead of clear demarcations between equally important conceptual areas, one finds marginal areas between categories that are only unambiguously defined in their focal points. This observation was taken over and elaborated by cognitive semanticists. Specifically, it was applied not just to the internal structure of a single word meaning, but also to the structure of polysemous words, i.e., to the relationship between the various meanings of a word. A popular descriptive model for charting that relationship is the radial set model, which graphically represents the way in which less central meanings branch out from the prototypical, core reading. Prototype theory, arguably the most influential contribution of cognitive linguistics to lexical semantics, receives a separate treatment in the article Prototype Theory in Linguistics.

Conceptual Metaphor and Metonymy

The interest in the internal structure of lexical items, as illustrated and embodied by the research covered in the previous subsection, automatically entails an interest in the semantic relations that interconnect the various readings of an item. Within a radial set for instance, the elements are not only connected through the fact that a less prototypical sense derives from a more central one, but also through a specific mechanism of semantic extension: similarity, or metaphor, or metonymy – basically, any of the mechanisms of meaning change that constituted the focus of historical semantics as discussed in the Section Prestructuralist Historical Semantics above.

Metaphor, in particular, constitutes a major area of investigation for cognitive semantics. The major impetus here came from Lakoff and Johnson (1980), a book that worked like an eye-opener for a new generation of linguists. In the linguistic climate of the 1970s, dominated by the formal framework of generative grammar, semantics seemed a peripheral issue, but *Metaphors We Live By*, more perhaps than the other foundational publications in cognitive semantics, was instrumental in putting semantics back on the research agenda.

Conceptual metaphor theory, the approach introduced by Lakoff, includes two basic ideas: first, the view that metaphor is a cognitive phenomenon rather than a purely lexical one; second, the view that metaphor should be analyzed as a mapping between two domains. To illustrate the first point, metaphor comes in patterns that transcend the individual lexical item. A typical example is the following.

LOVE IS A JOURNEY

Look how far we've come. We are at a crossroads. We'll just have to go our separate ways. We cannot turn back now. We are stuck. This relationship is a dead-end street. I don't think this relationship is going anywhere. It's been a long, bumpy road. We have gotten off the track.

The second pillar of conceptual metaphor theory is the analysis of the mappings inherent in metaphorical patterns. Metaphors conceptualize a target domain in terms of the source domain, and such a mapping takes the form of an alignment between aspects of the source and target. For LOVE IS A JOURNEY, for instance, the following correspondences hold.

Source	*Target*
The travelers	The lovers
The means of transport	The relationship itself
The journey	The development of the relationship
The obstacles encountered	The difficulties experienced
Decisions about which way to go	Choices about what to do
The destination of the journey	The goals of the relationship

The appeal of Conceptual Metaphor Theory engendered a revival of the interest in metonymy. In Lakoff and Johnson (1980), metonymy figured next to metaphor as one of the conceptual mechanisms behind the semantic structure of language. That clearly should not come as a surprise: an approach that is interested in the semantic mechanisms behind language use and linguistic structures is likely to rediscover the traditional mechanisms of semantic extension. Lakoff and Johnson list a number of metonymic patterns that might have been taken straightforwardly from a prestructuralist treatise on semantic change of the type that was discussed in the Section Prestructuralist Historical Semantics above. Lakoff and Johnson emphasize that such metonymic patterns are conceptual and not purely linguistic, in much the same way that metaphorical concepts are. In the first place, metonymical concepts allow us to think of one thing in terms of its relation to something else. In that sense, we can distinguish a source and target in the description of metonymy just like we can for metaphors. In the second place, metonymies are systematic in the sense that they form patterns that apply to more than just an individual lexical item.

Thus, the *bottle* example mentioned above exhibits the name of a container (source) being used for its contents (target), a pattern that can be abbreviated as 'container for contents.' Making use of this abbreviated notation, other common types of metonymy are the following: 'a spatial location for what is located there' (*the whole theater was in tears*); 'a period of time for what happens in that period, for the people that live then, or for what it produces' (*the nineteenth century had a nationalist approach to politics*); 'a material for the product made from it' (*a cork*); 'the origin for what originates from it' (*astrakhan, champagne, emmental*); 'an activity or event for its consequences' (when the *blow* you have received hurts, it is not the activity of your adversary that is painful, but the physical effects that it has on your body); 'an attribute for the entity that possesses the attribute' (*majesty* does not only refer to 'royal dignity or status,' but also to the sovereign himself); and of course 'part for whole' (*a hired hand*). The relations can often work in the other direction as well. *To fill up the car*, for instance, illustrates a type 'whole for part': it's obviously only a part of the car that gets filled. For the current state of affairs in metonymy research from a cognitive semantic point of view, see Benczes et al. (2011).

Frame Semantics

The models presented in the previous two subsections illustrate two important features of cognitive semantics: the interest for the contextual flexibility of meaning (as reflected in prototype-based models for describing polysemy and semantic nuances), and the tight links between language and thinking in general (as illustrated by conceptual metaphor and metonymy research). A third feature of cognitive semantics that needs to be mentioned in this respect is its interest in the way our knowledge of the world is organized in larger 'chunks of knowledge,' and how these interact with language. The most articulate model in this respect is Fillmore's frame theory (Fillmore and Atkins, 1992). Frame theory is specifically interested in the way in which language may be used to perspectivize an underlying conceptualization of the world: it's not just that we see the world in terms of conceptual models, but those models may be verbalized in different ways. Each different way of bringing a conceptual model to expression so to speak adds another layer of meaning: the models themselves are meaningful ways of thinking about the world, but the way we express the models while talking adds perspective. This overall starting-point of Fillmorean frame theory leads to a description on two levels. On the one hand, a description of the referential situation or event consists of an identification of the relevant elements and entities and the conceptual role they play in the situation or event. On the other hand, the more purely linguistic part of the analysis indicates how certain expressions and grammatical patterns highlight aspects of that situation or event.

To illustrate, we may have a look at the standard example of frame theory, the COMMERCIAL TRANSACTION frame. The commercial transaction frame involves words like *buy* and *sell*. The commercial transaction frame can be characterized informally by a scenario in which one person gets control or possession of something from a second person, as a result of a mutual agreement through which the first person gives the second person a sum of money. Background knowledge involved in this scenario includes an understanding of ownership relations, a money economy, and commercial contracts. The categories that are needed for describing the lexical meanings of the verbs linked to the commercial transaction scene include Buyer, Seller, Goods, and Money as basic categories. Verbs like *buy* and *sell* then each encode a certain perspective on the commercial transaction scene by highlighting specific elements of the scene. In the case of *buy*, for instance, the buyer appears in the participant role of the agent, for instance as the subject of the (active) sentence. In active sentences, the goods then appear as the direct object; the seller and the money appear in prepositional phrases: *Paloma bought a book from Teresa for €30*. In the case of *sell* on the other hand, it is the seller that appears in the participant role of the agent: *Teresa sold a book to Paloma for €30*.

Basic Levels and Onomasiological Salience

Possibly the major innovation of the prototype model of categorization is to give salience a place in the description of semasiological structure: next to the qualitative relations among the elements in a semasiological structure (like metaphor and metonymy), a quantifiable center–periphery relationship is introduced as part of the architecture. But the concept of salience can also be applied to the onomasiological domain. (Semasiology looks at the relationship between words and meaning with the word as starting point: it is basically interested in the polysemy of words. Onomasiology takes the converse perspective: given a concept to be expressed or a thing to be categorized, what options does a language offer, and how are the choices made?)

The initial step in the introduction of onomasiological salience is the *basic-level hypothesis*. The hypothesis is based on the ethnolinguistic observation that folk classifications of biological domains usually conform to a general organizational principle, in the sense that they consist of five or six taxonomical levels (Berlin, 1978). The basic-level hypothesis embodies a notion of onomasiological salience because it is a hypothesis about alternative categorizations of referents: if a particular referent (a particular piece of clothing) can be alternatively

categorized as a garment, a skirt, or a wraparound skirt, the choice will be preferentially made for the basic-level category 'skirt.' But differences of onomasiological preference also occur *among* categories on the same level in a taxonomical hierarchy. If a particular referent can be alternatively categorized as a wraparound skirt or a miniskirt, there could just as well be a preferential choice: when you encounter something that is both a wraparound skirt and a miniskirt, the most natural way of naming that referent in a neutral context would probably be 'miniskirt.' If, then, we have to reckon with intralevel differences of salience next to interlevel differences, the concept of onomasiological salience has to be generalized in such a way that it relates to individual categories at any level of the hierarchy.

This notion of *generalized onomasiological salience* was first introduced in Geeraerts et al. (1994). Using corpus materials, this study established that the choice for one lexical item rather than the other as the name for a given referent is determined by the semasiological salience of the referent (i.e., the degree of prototypicality of the referent with regard to the semasiological structure of the category), by the overall onomasiological salience of the category represented by the expression, and by contextual features of a classical sociolinguistic and geographical nature, involving the competition between different language varieties. By zooming in on the latter type of factor, a further refinement of the notion of onomasiological salience is introduced, in the form of the distinction between *conceptual* and *formal* onomasiological variation. Whereas conceptual onomasiological variation involves the choice of different conceptual categories for a referent (like the examples presented so far), formal onomasiological variation merely involves the use of different synonymous names for the same conceptual category. The names *jeans* and *trousers* for denim leisure wear trousers constitute an instance of conceptual variation, for they represent categories at different taxonomical levels. *Jeans* and *denims*, however, represent no more than different (but synonymous) names for the same denotational category.

It is further observed that all types of lexical variation may be subject to contextual, 'lectal' variation. Different dialects may use words in different meanings (semasiological variation). Experts are more likely to use specific, technical terms than laymen (conceptual onomasiological variation). And denotationally synonymous expressions may have different sociolinguistic distributions (formal onomasiological variation). This recognition then leads to an upsurge of sociolexicological studies, as part of cognitive sociolinguistics, i.e., the study of language variation from a cognitive linguistic point of view: see Kristiansen and Dirven (2008).

Overview and Outlook

The development of linguistic lexical semantics appears to be characterized by a succession of distinct theories. Crucially, each of the competing theoretical frameworks has contributed to the descriptive expansion of lexical semantics, i.e., each of them has drawn the attention to specific phenomena. Focusing on the major phenomena, these contributions successively include the links between the various senses of words in prestructuralist historical semantics, the semantic relationships within the vocabulary in the structuralist era, and the importance of semasiological and onomasiological salience effects in cognitive semantics. Regardless of the theoretical oppositions, these phenomena all belong to the descriptive scope of current lexical semantics: the emergence of new points of attention has not made the older topics irrelevant. To give just one example, prototype theory may trigger a reconsideration of what it means for two words to be synonymous, but the notion of synonymy remains a serious topic of investigation for lexical semantics.

Next to the theoretical shifts and the descriptive expansion, a methodological evolution characterizes the historical path of lexical semantics: a structuralist focus on syntagmatic relations, boosted by the growing availability of text corpora, has led to a distributional method of corpus-based semantics. Together with the theoretical and descriptive innovations introduced by cognitive semantics, this new quantitative and computational method is likely to shape the evolution of lexical semantics in the following years.

Lexicology and Lexicography

Wolfgang Klein, Max Planck Institut für Psycholinguistik, Nijmegen, The Netherlands

Abstract

Lexicology is the scientific investigation of the lexicon of a language, including, for example, its historical development, its social stratification, its quantitative composition, or the way in which some thematic area is encoded. Lexicography, the oldest subdiscipline of linguistics, deals with the compilation of dictionaries. There are many types of dictionaries, depending mainly on which lexical units are included, and which of their properties – such as sound, spelling, grammatical features, meaning, etymology, and others – are described. Two technological innovations are crucial to the presentation of lexical information – the art of printing, which led to the familiar printed dictionary, and the computer, which makes it possible to build up and to exploit large data sources and to develop complex digital lexical systems.

Introduction

Each language has a lexicon and a grammar, i.e., a set of elementary expressions and a set of rules according to which complex expressions are constructed from simpler ones. Some of these rules form complex words; others operate beyond the boundaries of the word, thus producing phrases and sentences. These distinctions, familiar from the days of the Greek grammarians, are not always clear-cut, for at least two reasons. First, the notion of 'word' is not very well defined. Second, there are complex expressions, whose meaning is more or less predictable from the meaning of its components, whereas this is not true for other complex expressions. The former are said to be 'compositional,' whereas the latter are 'lexicalized'; slightly different terms to characterize this opposition are 'productive' vs 'idiomatic,' and 'free' vs 'fixed'; in each case, the distinction is gradual. Lexicalization is rarely observed for inflected words (a possible exception are 'participles' such as *crooked* in *a crooked street*), but very frequent for compound words, such as *landlord* or (*to*) *withdraw*, or phrases such as *to kick the bucket*, which has a compositional as well as a lexicalized reading. Do lexicalized expressions belong to the lexicon of a language or to its grammar? There is no straightforward answer; their form is complex and rule based, their meaning is not. Therefore, it is useful to take the term 'lexicon' in a somewhat broader sense; it contains all elementary expressions (= lexicon in the narrower sense) as well as those expressions which are compound in form but not accordingly in meaning (*see* Lexicon). The scientific investigation of the lexicon in this sense is usually called lexicology; it includes, for example, the historical development of the lexicon, its social stratification, its quantitative composition, or the way in which some subfield is encoded in lexical items (e.g., 'terminology of hunting,' 'verbs of movement'). Lexicography, by contrast, deals with the compilation of dictionaries. There is considerable overlap between both disciplines, and in fact, not all authors make such a terminological distinction.

The Lexicon

The lexicon of a language is stored primarily in the head of its speakers, and for most of the history of mankind, it was only stored there. We do not know what form the 'mental lexicon' has (*see* Psycholinguistics: Overview). There is agreement, however, that it consists of individual lexical units which are somehow interrelated to each other. There is no generally accepted term for lexical units. The familiar term 'word' is both too broad and too narrow; one would not want to consider *goes* as a lexical unit, although it is a word, whereas expressions such as (*to*) *knock out* or *red herring* are lexical units but consist of several words. Other terms occasionally found are 'lexeme,' 'lemma,' or 'lexical entry,' but since these are also used in other ways, it is probably best to speak of lexical units.

It is important to distinguish between a lexical unit and the way in which it is named. The word *house* in a dictionary, followed by all sorts of explanations, is not the lexical unit – it is a name for such a unit. The lexical unit itself is a bundle of various types of properties. These include:

1. phonological properties, which characterize how the lexical unit is pronounced; they include sounds, syllabic structure, lexical accent and, in some languages, lexical tone;
2. graphematic properties, which characterize how the lexical unit is written (*see* Spelling, Psychology of);
3. morphosyntactic properties, which characterize how the unit can become part of more complex expressions; typically, they concern word class, inflectional paradigm, and government relations;
4. semantic properties, which concern the 'lexical meaning' of the unit, i.e., the contribution which it makes to the meaning of the construction in which it occurs.

Some of these properties may be absent. This is most obvious for graphematic properties, since not all languages are written. There are a few lexical units without lexical meaning, such as the expletive *there* in English. Many linguists also stipulate 'zero elements,' i.e., units with morphosyntactic and semantic properties but without phonological properties (such as 'empty pronouns'); but these are normally treated in the grammar rather than in the lexicon.

Whereas these four types of properties are the defining characteristics of a lexical unit, other information may be associated with it, for example, its etymology, its frequency of usage, its semantic counterpart in other languages, or encyclopedic knowledge (thus, it is one thing to know the

meaning of *bread* and a different thing to know various sorts of bread, how it is made, its price, its role in the history of mankind, etc.).

The lexical units of a lexicon are in many ways interrelated. They may share some phonological properties (for example, they may rhyme with each other), they may belong to the same inflectional paradigm, they may have the opposite meaning ('antonyms,' such as *black* and *white*), approximately the same meaning ('synonyms,' such as *to begin* and *to start*), or when complex in form they may follow the same construction pattern. Lexicological research is often oriented toward these interrelations, whereas lexicography tends to give more weight to the lexical unit in itself. In general, there is much more lexicographical than lexicological work (for a survey of the latter, see Cruse et al., 2005); in fact, if there is any piece of linguistic description for some language, it is probably an elementary bilingual dictionary. The depth of this work varies massively not only across languages, but also with respect to the particular lexical properties. Whereas the phonological, graphematic, and morphosyntactic features of the lexicon in Latin, English, French, and some dozen other languages with a comparable research tradition are fairly well described, there is no theoretically and empirically satisfactory analysis of the semantics of the lexicon for any language whatsoever. This has three interrelated reasons. First, there is no well-defined descriptive language which would allow the researcher to represent the meaning of some lexical unit, be it simple or compound; the most common practice is still to paraphrase it by an expression of the same language. Second, there is no reliable and easily applicable method of determining the lexical meaning of some unit; the most common way is to look at a number of occurrences in ongoing text and to try to understand what it means. Third, the relation between a particular form and a particular meaning is hardly ever straightforward; this is strikingly illustrated by a look at what even a medium-sized English dictionary has to say about the meaning of, for example, *on*, *sound*, *cast*, or (*to*) *put*. As a rule, there is not just one lexical meaning, but a whole array of uses, which are more or less related to each other. This is not merely a practical problem for the lexicographer; it also casts some doubt on the very notion of 'lexical unit' itself (*see* Lexical Semantics).

Making Dictionaries

Lexicographers often consider their work to be more of an art or a craft than a science (see Svensén, 2009). This does not preclude a solid scientific basis, but it reflects the fact that their concrete work depends largely on practical skills such as being 'a good definer,' on the one hand; and that it is to a great extent determined by practical, often commercial, concerns, on the other. Dictionaries are made for users, and they are intended to serve specific purposes. Their compilation requires a number of practical decisions.

Which Lexical Units Are Included?

Languages are neither well defined nor uniform entities; they change over time, and they vary with factors such as place, social class, or area talked about. A great deal of this variation is lexical. It is not possible nor would it be reasonable to cover this wealth in a single dictionary. Large dictionaries contain several hundred thousands of 'entries'; since idiomatic expressions are usually listed under one of their components (such as *to kick the bucket* under (*to*) *kick*), they contain many more lexical units, perhaps up to one million. But, even so, they are by no means exhaustive. The second edition of the *Deutsches Wörterbuch* (see Section Shortcomings), the largest dictionary of German, covers less than 25% of the lexical units found in the sources, and these sources are quite restricted themselves.

Which Lexical Properties Are Described?

Just as it is impossible to include all lexical units of a language in a dictionary, it is neither possible nor desirable to aim at a full description of those which are included. Since a dictionary is traditionally a printed book, the graphematic properties of the unit (its 'spelling') are automatically given. Among the other defining properties, meaning is traditionally considered to be most important. Samuel Johnson's dictionary from 1755 (see Section Shortcomings) defines 'dictionary' as "A book containing the words of any language in alphabetical order, with explanations of their meaning." But Johnson also noted which syllable carries the main stress, and he gave some grammatical hints. In general, however, information on phonological properties was rare up to the end of the nineteenth century, and information on grammatical properties is usually still very restricted in nonspecialized dictionaries. But there are, of course, also dictionaries which specifically address these properties as well as some of the nondefining properties associated with a lexical entry, such as its origin (etymological dictionary) or, above all, its equivalent in other languages ('bilingual dictionary').

What Is the Description Based Upon?

Usually, two types of sources are distinguished: 'primary sources' are samples of text in which the unit is used, 'secondary sources' refer to prior work of other lexicographers (and lexicologists). In fact, there is a third source, normally not mentioned in the theory of lexicography: This is the lexicographer's own knowledge of the language to be described, including his or her views on what is 'good' language. In practice, the bulk of a new dictionary is based on older dictionaries. This is always immoral and often illegal, if these are simply copied; but on the other hand, it would be stupid and arrogant to ignore the achievements of earlier lexicographers.

How Is the Information Presented?

A dictionary consists of lexical entries arranged in some conventional order. Normally, an entry combines several lexical units under a single 'headword'; thus, all lexical units which include the word *put* may be listed under this headword, forming a kind of nest with an often very complex microstructure. We are used to alphabetically ordered dictionaries; but there are other possibilities, for example, by thematic

groups or by first appearance in written documents. Languages without alphabetic writing require different principles; in Chinese, for example, entries are usually arranged by subcomponents of the entire character and by the number of strokes.

These four questions can be answered in very different ways, resulting in very different types of dictionaries (see the survey in Hausmann et al., 1991: 968–1573).

History

The first lexicographic documents are lists of Sumerian words (up to 1400) with their Akkadian equivalents, written in cuneiform script on clay tablets about 4700 years ago. The practice of compiling such word lists was continued throughout Antiquity and the Middle Ages; thus, the oldest document in German, the *Abrogans* (written around 765), is an inventory of some Latin words with explanations in German. Usually, these 'glossaries' did not aim at a full account of the lexicon; they simply brought together a number of words which, for one reason or another, were felt to be 'difficult,' and explained them either by a more familiar word in the same language or by a translation. Words were ordered alphabetically, by theme, or not at all. But there are also more systematic attempts, such as the *Catholicon*, a mixture of encyclopedia and dictionary which, compiled around 1250, was the first printed lexical work in Europe (Mainz 1460).

In the sixteenth century, two developments led to major changes. The first of these was the invention of printing by Gutenberg. By 1500, virtually all classical authors were available in print, thus offering a solid basis for systematic lexical accounts of Latin and Greek, such as Calepinus' *Dictionarium* (Dictionary) (1502), soon to be followed by two early masterpieces: Robert Etienne's *Dictionarium seu Latinae Linguae Thesaurus* (*Dictionary or Thesaurus of the Latin Language*) (Paris 1531) and Henri Etienne's *Thesaurus Graecae Linguae* (*Thesaurus of the Greek Language*) (Paris 1572). The second major development was the slow but steady rise of national languages. Since early Italian, French, English, or German were hardly codified, a major aim of the first dictionaries in these languages was to give them clear norms. In some countries, national Academies were founded to this end. The outcome were dictionaries with a strongly normative, often puristic, stance, such as the *Vocabulario degli Academici della Crusca* (*Vocabulary of the Members of the Academia della Crusca*) (Venice 1612), the *Dictionnaire de l'Académie Française* (*Dictionary of the French Academy*) (Paris 1694), and the *Diccionario de autoridades publicado por la Real Academia Espanola* (*Dictionary of the Authorities published by the Royal Spanish Academy*) (1726–1739). The bulk of lexicographic work, however, was always done by enterprising publishers and engaged individuals, such as Dr Samuel Johnson. Helped by six assistants, he produced *A Dictionary of the English Language* (London 1755), the first scholarly description of the English vocabulary, in less than 8 years. It surpassed all its predecessors, including Bailey's *Dictionarium Britannicum* (*British Dictionary*) from 1736, which Johnson took as his point of departure, by the systematic use of quotations, taken from the 'best writers,' and by his brilliant, sometimes somewhat extravagant, definitions (not everybody would dare to characterize patriotism as 'the last refuge of a scoundrel').

The rise of historical–comparative linguistics in the early nineteenth century led to an enormous increase in grammatical and lexical knowledge. The first dictionary which tried to cover this knowledge was the *Deutsches Wörterbuch* (*German Dictionary*) by Jacob Grimm and (to a lesser extent) his brother Wilhelm. Its first fascicle appeared in 1852, after about 10 years of preparatory work, in which the Grimms were helped by about 100 scholars providing excerpts ("covering my desk like snowflakes," Jacob Grimm). At that time, it was already clear that the original plan of six to seven volumes, to be finished within 10–12 years, was unrealistic. The Grimms finished only letters A to (most of) F, and the final folio volume (of altogether 32) appeared in 1961. This long duration, as well as the varying talents and preferences of the contributors, has led to many inconsistencies; some entries got out of balance (no less than 60 folio pages are devoted to the single word *Geist* (mind, spirit, ghost)); still, it is an incommensurable source of lexical information.

The work of the Grimms inspired a number of similar ventures, such as Emile Littré's masterly *Dictionnaire de la langue française* (*Dictionary of the French Language*) (1863–73), which is much shorter, but also much more consistent; Matthias de Vries and his numerous successors' voluminous *Woordenboek der Nederlandsche Taal* (*Dictionary of the Dutch Language*) (1864–1998), and finally *A New English Dictionary on a Historical Basis* (1884–1928), generally referred to as the *Oxford English Dictionary* (OED). It was initiated in 1857 by the philologist and churchman Richard Trench; in 1860, members of the Philological Society started to collect excerpts; in 1879, the Clarendon Press appointed James Murray as the Principal Editor. The first fascicle appeared in 1882, and the whole work was completed in 1928, 13 years after Murray's death. More than 200 scholars were involved in its production, more than 2000 people are known to have contributed excerpts. The OED is not without flaws, even in its revised edition, which appeared in 1989 in print and in 1992 on CD-ROM; but among all attempts to describe the lexicon of a language, it comes closest to falsify what Dr Johnson stated in the preface to his own dictionary: "Every other author may aspire to praise; the lexicographer can only hope to escape reproach." (For a comprehensive survey of lexicographic work across languages, see Hausmann et al., 1991: 1679–2710, 2949–3119.)

Shortcomings

At the end of the twentieth century, the art of making dictionaries had reached a remarkable degree of perfection. But two reservations are in order here. First, this perfection only holds for about 5% of the about 7000 languages of the world; for all others, we only have only more or less fragmentary and often unreliable accounts of their lexical repertoire – if any. Second, even the best dictionaries have individual as well as systematic shortcomings. Lexicographers are human beings, and thus, there are individual errors, poor definitions, or arguable decisions that make their achievements imperfect and popular targets of criticism. But there are

also deficiencies that result from the very nature of the printed book itself. These include:

1. Size restrictions. In a comprehensive corpus of present-day German, we find about five million lexical units (not counting dialects); the largest dictionary of present-day German describes about 170 000 lexical units – in 10 volumes, thus less than 5% of the words that are actually used.
2. Inadequacies of description. As a rule, the information given in a dictionary grossly underspecifies the various properties of a lexical item. Phonological properties are characterized by a phonetic script, such as the International Phonetic Alphabet (IPA); but from such a transcription, most users can only guess what a word really sounds like. The grammatical properties of a word are normally much more complex than what can be described by simple indications such as 'noun' or 'transitive verb.' Hardly anyone understands which familiar English words are targeted at by the meaning descriptions "Before the time in question, beforehand; by now; as early or as soon as this" or "diversion, amusement, sport; also, boisterous, jocularity or gaiety, drollery. Also, a source or cause of amusement or pleasure." (This is how the OED – the best dictionary of the world – describes the main readings of *already* and *fun*, respectively.)
3. Exclusion of overarching lexical properties. The vocabulary of a language is not just an aggregation of individual words, it is a highly complex structure, defined by the many relations which obtain between the phonological, grammatical, and semantical properties of all words (*see* Lexicon). A traditional dictionary with its focus on individual lexical units can hardly account for this aspect of a lexicon.

Since these deficiencies reflect inherent limits of a printed book – and this is what we normally understand a dictionary to be – it is practically impossible to overcome them within the limits of that format. Other formats must be developed to compile and to present lexical information. It is the advent of digital methods which begins to make this possible.

Digital Lexicography

Over the last decades, digital methods began to change, and in fact to overthrow, traditional lexicography. Five main lines in this development can be distinguished. First, it was necessary to create specific dictionaries for various tasks of natural language processing, such as machine translation, man–machine dialogue systems, or automatic text analysis. These 'dictionaries' are sometimes based on a machine-readable version of an existing printed dictionary. But the lexical information is stored on the computer, and it is given by some formal representation, rather than in a natural language. In the event, this led to completely new ways to describe the meaning of lexical units: the classical paraphrase in a few words was replaced by a netlike structure, in which various elements which play a role for that word are connected by semantic relations such as 'is a,' 'is a part of,' 'entails,' etc. The best known of these systems are WordNet (developed in Princeton) and FrameNet (developed in Berkeley).

Second, there is an increasing number of databases, mostly accessible via the Internet, which provide computer-generated information about various lexical properties of a language, for example, the frequency of words (or parts of words such as graphemes and morphemes) or of word co-occurrences. Good examples are the databases at the Brigham Young University (http://view.byu.edu) for English, the *Centre National de resources textuelles et lexicales* (National Center for textual and lexical resources) (www.cnrtl.fr) for French or *Wortschatz* (Vocabulary) (http://corpora.informatik.uni-leipzig.de), which provides statistical information about word frequencies and collocations in about 230 languages. Such databases often exploit huge corpora, sometimes in the range of billions of words. But these corpora are mostly not carefully compiled but based on material that happens to be available in digital form (like recent newspapers or Wikipedia texts), and, more importantly, their analysis is based on bare written word forms, without looking at the meaning. Thus, homographs such as *bear* and *bear* or *left* and *left* are considered as the same lexical item; this may limit their reliability for lexicology and lexicography.

Third, existing printed dictionaries were transferred to the computer and adapted to the purposes of the common user. Such a transfer offers several advantages: Search is faster and more exhaustive; the information is easier to revise and to update; and it is possible to add information not available in book format, for example, spoken sound instead of phonetic transcriptions. There are an increasing number of mostly free web sites which contain links to or even host dozens of – mostly bilingual – dictionaries, such as www.lexilogos.com, dictionary.cambridge.org, or www.dict.cc. They offer a cheap, fast, and easy source of lexical information, whose quality, though, varies considerably. Revisions and amendments, if there are any, are largely in the hands of volunteers.

Fourth, computers were increasingly used as tools in the *production* of a new dictionary. Rather than having a number of people read through books and newspapers and make excerpts of all occurrences which look interesting, it is now possible to compile huge text corpora that cover all varieties of a language, to scan these texts for all occurrences of words or word combinations, to sort these occurrences by various criteria, to link them to other occurrences, to add as much context as needed, etc. (Atkins and Rundell, 2008; *see* Corpus Linguistics). The first OED was based on about five million excerpts, mostly handwritten on paper slips. A computer can easily process corpora of several hundred million words, i.e., several hundred million occurrences; new sources can rapidly be added. This allows a much broader and much more representative coverage of a lexicon than ever. But electronic corpora only provide the raw material; it still awaits lexical analysis. This analysis can be facilitated by computer tools, also; but no computer can tell us what a word means in a particular context. If only 1 min is devoted to each occurrence in a one billion word corpus, it would take 100 lexicographers 100 years to go through it. This means that printed dictionaries can never reflect the wealth of information accessible in large corpora, because they are outdated when the lexicographers come to the end of their analysis. Therefore, the most recent version of the OED is no longer a printed book but a regularly updated and expanded computer

dictionary that is only searchable over the Internet (www.oed.com).

The fifth and last development is complex *digital lexical systems* which integrate various sources of information. They consist of (1) a computer-accessible and expandable corpus, (2) a set of tools, which allow, for example, not only the search for certain items but also statistical analysis or the determination of the first occurrence, or just look up of a number of occurrences that illustrate the use of an unknown word, and (3) a selective but steadily proceeding lexical analysis of the corpus by experienced lexicographers; in that respect, they are in line with the established lexicographical tradition. According to the need of the users and the means that are available, this analysis may vary in depth and coverage. Thus, it is possible to add spoken forms in various dialects, information about word classes, or the semantic analysis of some subset of lexical units, say all prepositions or all morphologically simple verbs. Similarly, translation equivalents can be added. Unlike printed dictionaries, such a lexical retrieval system, such as the *Digitale Wörterbuch der Deutschen Sprache* (*Digital Dictionary of the German Language*) (www.dwds.de), will never come to an end, it is steady work in progress to which many can contribute and which will give us a deeper and broader understanding of the lexicon than any other method.

Abstract

The lexicon is standardly viewed as a listing of all the morphemes of a language, with information indicating how each morpheme behaves in the components of grammar involving phonology, syntax, and semantics.

The Notion of Lexicon

The lexicon is standardly viewed as a listing of all the morphemes of a language, with information indicating how each morpheme behaves in the components of grammar involving phonology, syntax, and semantics. In no small part, the shape and character of grammar is determined by what the lexicon contains for these other grammatical devices. Nevertheless, both historically and conventionally, the lexicon has been seen as the passive module in the system of grammar.

More recently, the model of the lexicon has undergone significant revision and maturation. In particular, two trends have driven the architectural concerns of lexical researchers: (1) a tighter integration of compositional operations of syntax and semantics with the lexical information structures that bear them; and (2) a serious concern with how lexical types reflect the underlying ontological commitments of the grammar. In the process, the field has moved toward addressing more encompassing problems in linguistic theory, such as those below:

1. How can we explain the polymorphic nature of language?
2. How can we capture the creative use of words in novel contexts?
3. How can semantic types predictably map to syntactic representations?
4. What are the 'atoms' of lexical knowledge, if they exist at all?

In this article, we first review the conventional view of the lexicon and then contrast this with the theories of lexical information that have emerged since around 1990.

By all accounts, the conventional model of the lexicon is that of a database of words, ready to act in the service of more dynamic components of the grammar. This view has its origins squarely in the generative tradition (Chomsky, 1955) and has been an increasingly integral part of the concept of the lexicon ever since. While the 'Aspects' model of selectional features restricted the relation of selection to that between lexical items, work by Jackendoff (1972) and McCawley (1968), showed that selectional restrictions must be available to computations at the level of derived semantic representation rather than at deep structure. But where did this view come from? In order to understand both the classical model of the lexicon as a database and the current models of lexically encoded grammatical information, it is necessary to appreciate the structuralist distinction between 'syntagmatic processes' and 'paradigmatic systems' in language. The lexicon has emerged as the focal point communicating between these two components, and can be seen as a hook which links the information at these two levels. One can go further still and view the elements of the lexicon as not just the building blocks for the more active components of the grammar, but also as actively engaging the building principles themselves.

While syntagmatic processes refer to the influence of horizontal elements on a word or phrase, paradigmatic systems refer to vertical substitutions in a phrasal structure. Syntagmatics evolved into the theory of abstract syntax while paradigmatics was all but abandoned in generative linguistics. In an early discussion of syntagmatic dependencies, Hjelmslev (1943) uses the term 'selection' explicitly in the modern sense and notes the importance of integrating paradigmatic systems with the syntagmatic processes they participate in. For Hjelmslev, there are two possible types of relations that can exist between elements in a syntagmatic process: 'interdependence' and 'determination,' the latter of which is related to the notion of selectional restriction as developed by Chomsky (1965). As Cruse (1986) notes "One reason that selectional restrictions were not integrated into mechanisms of grammatical selection and description in the 1970s and 1980s is that, if they are imposed correctly, the grammar is forced to model two computations:

1. The entailment relations between selectional restrictions as features must be modeled formally, in order to contribute to the computation of a syntactic description;
2. The manner in which selectional features or constraints contribute to the determination of the meaning of expressions must be enriched in order to exploit these very features."

Recently, with the convergence of several areas in linguistics (lexical semantics, computational lexicons, and type theories) several models for the determination of selection have emerged which actively integrate these central syntagmatic processes into the grammar, by making explicit reference to the paradigmatic systems which allow for grammatical constructions to be partially determined by selection. Examples of this approach are Generative Lexicon Theory (Bouillon and Busa 2001; Pustejovsky, 1995), and to a certain extent, Construction Grammar (Goldberg, 1995), Combinatory Categorical Grammar (CCG) (Steedman, 1997), and Head-driven Phrase Structure Grammar (HPSG) (Pollard and Sag, 1994).

These recent theoretical developments have led to a new direction in lexical design. Rather than restricting the scope of

the lexicon to that of a passive database, current frameworks have rearchitected the relationship between syntactic and semantic representations and the underlying recurrence relations that generate them. These developments have helped to characterize the approaches to lexical design in terms of a hierarchy of semantic expressiveness. There are at least three such classes of lexical description, which are defined (cf Pustejovsky, 1995 for discussion):

1. Sense Enumerative Lexicons: lexical items have a single type and meaning, and ambiguity is treated by multiple listings of words.
2. Polymorphic Lexicons: lexical items are active objects, contributing to the determination of 'meaning in context' under well-defined constraints.
3. Unrestricted Sense Lexicons: meanings of lexical items are determined mostly by context and conventional use. Few, if any, restrictions are imposed on how a word may refer.

Although there have been proponents for each class of lexical description defined here, the most promising direction seems to be a careful and formal elucidation of the polymorphic lexicons, and this will form the basis of our subsequent discussion of both the structure and content of lexical entries.

The Structure of a Lexical Entry

As mentioned in Section The Notion of Lexicon, it is generally agreed that there are three components to a lexical item: phonological, syntactic, and semantic information. In this entry, we mainly focus on the manner in which syntactic and semantic representations are encoded in the lexical entry.

There are two types of syntactic knowledge associated with a lexical item: its 'category' and its 'subcategory.' The former includes traditional classifications of both the major categories, such as noun, verb, adjective, adverb, and preposition, as well as the minor categories, such as adverbs, conjunction, quantifier elements, and determiners (*see* Parts of Speech).

Knowledge of the subcategory of a lexical item is typically information that differentiates categories into distinct, distributional classes. This sort of information may be usefully separated into two types, 'contextual features' and 'inherent features.' The former are features that may be defined in terms of the contexts in which a given lexical entry may occur. Subcategorization information marks the local syntactic context for a word. It is this information that ensures that the verb 'devour,' for example, is always transitive in English, requiring a direct object; the lexical entry encodes this requirement with a subcategorization feature specifying that an Noun Phrase (NP) appear to its right. Another type of context encoding is collocational information, where patterns that are not fully productive in the grammar can be tagged. For example, the adjective 'heavy' as applied to 'drinker' and 'smoker' is collocational and not freely productive in the language (Mel'čuk 1988). 'Inherent features,' on the other hand, are properties of lexical entries that are not easily reduced to a contextual definition, but rather refer to the ontological typing of an entity. These include such features as count/mass (e.g., 'pebble' vs 'water,' abstract, animate, human, physical, and so on).

Semantic information can also be separated into two categories: 'base semantic typing' and 'selectional typing.' While the former identifies the semantic class that a lexical item belongs to (such as entity, event, property), the latter class specifies the semantic features of arguments and adjuncts to the lexical item.

Word Classes and Typing Information

There are two major approaches to classifying lexical items by their type: syntactic and semantic. (Another influential tradition for verb classification, which we will not discuss in detail here, is a more descriptive approach to word classes, where membership is defined on the basis of grammatical behavior and verbal valency alternation, such as that elaborated on and compiled in Levin, 1993).

One obvious way to organize lexical knowledge, be it syntactic or semantic, is by means of lexical inheritance mechanisms. In fact, much recent work has focused on how to provide shared data structures for syntactic and morphological knowledge (Flickinger et al., 1985). Evans and Gazdar (1990) provide a formal characterization of how to perform inferences in a language for multiple and default inheritance of linguistic knowledge. The language developed for that purpose, DATR, uses value terminated attribute trees to encode lexical information. Briscoe et al. (1993) describe a rich system of types for allowing default mechanisms into lexical type descriptions.

Type structures can express the inheritance of syntactic features (Sanfilippo, 1993) as well as the relationship between more conventional taxonomic information, such as that shown in Section Argument Structure (cf Copestake and Briscoe, 1992; Pustejovsky, 1995; Pustejovsky and Boguraev, 1993) and **Figure 1**.

Given a semi-lattice of types such as this, the lexical items in the language can be associated with a much richer system of differentiated semantic classes. Verbs may also be structured in hierarchical relations, as done in HPSG, Lexical Functional Grammar (LFG), and other lexical frameworks (cf Pollard and Sag, 1994; Alsina, 1992; Koenig and Davis, 1999).

Argument Structure

Once the base syntactic and semantic typing for a lexical item has been specified, its subcategorization and selectional information must be encoded in some form. There are two major techniques for representing this type of knowledge:

1. associate 'named roles' with the arguments to the lexical item;

Figure 1 Fragment of a type hierarchy.

2. associate a logical decomposition with the lexical item; meanings of arguments are determined by how the structural properties of the representation are interpreted (cf Hale and Keyser, 1993; Levin and Rappaport, 1995; Pustejovsky, 1995).

One influential way of encoding selectional behavior is the theory of thematic relations (cf Gruber, 1976; Jackendoff, 1972). Thematic relations are typically defined as partial semantic functions of the event being denoted by the verb or noun, and behave according to a predefined calculus of roles relations (e.g., Carlson, 1984; Dowty, 1989). For example, semantic roles such as agent, theme, and goal can be used to partially determine the meaning of a predicate, when they are associated with the grammatical arguments to a verb.

The theory of argument structure as developed by Williams (1981), Grimshaw (1990), and others can be seen as a move toward a more minimalist description of semantic differentiation in the verb's list of parameters. The argument structure for a word can be seen as the simplest specification of its semantics, indicating the number and type of parameters associated with the lexical item as a predicate. For example, the verb 'build' can be represented as a predicate taking two arguments, while the verb 'give' takes three arguments.

1.
   a. build ($\underline{x}$, y)
   b. give ($\underline{x}$, y, z)

What originally began as the simple listing of the parameters or arguments associated with a predicate has developed into a sophisticated view of the way arguments are mapped onto syntactic expressions. Williams' (1981) distinction between 'external' (the underlined arguments) and 'internal' arguments and Grimshaw's proposal for a hierarchically structured representation (cf Grimshaw, 1990) provide us with the basic syntax for one aspect of a word's meaning. Similar remarks hold for the argument list structure in HPSG (Pollard and Sag, 1994) and LFG (Bresnan, 1994).

The interaction of a structural argument list and a rich system of types, such as that presented, provides a mechanism for semantic selection that overcomes the difficulties mentioned in Section The Structure of a Lexical Entry. The most direct impact of semantic type systems on syntactic subcategorization can be seen with the analysis of a simple example.

2.
   a. The man/the rock fell.
   b. The man/*the rock died.

Returning to the example in (2), consider how the selectional distinction for the feature [+/− animacy] is modeled. For the purpose of illustration, the arguments of a verb will be represented in a list structure, where each argument is identified as being typed with a specific value.

3.
   a. $\begin{bmatrix} \text{fall} \\ \text{ARGSTR} = [\text{ARG}_1 = \text{x} : \text{phys_obj}] \end{bmatrix}$
   b. $\begin{bmatrix} \text{die} \\ \text{ARGSTR} = [\text{ARG}_1 = \text{x} : \text{animate}] \end{bmatrix}$

In the sentences in (2), it is intuitively clear how rocks cannot die and men can but it is still not obvious how this inference is computed, given what we would assume are the types associated with the nouns 'rock' and 'man' respectively. What accomplishes this computation is a rule of subtyping, Θ, that allows the type associated with the noun 'man' (i.e., human) to also be accepted as the type animate, which is what the predicate 'die' requires of its argument as stated in (3b)

4. Θ [human $\sqsubseteq$ animate]: human $\rightarrow$ animate

The rule Θ applies, since the concept human is subtyped under animate in the type hierarchy. Parallel considerations rule out the noun 'rock' as a legitimate argument to 'die' since it is not subtyped under animate. Hence, one of the concerns given for how syntagmatic processes can systematically keep track of which 'selectional features' are entailed and which are not is partially addressed by such lattice traversal rules as the one presented here.

Selection can also be employed to solve the problem of polymorphism, where the same lexical item can appear in multiple syntactic contexts, as illustrated in (5) below.

5.
   a. Mary began to read the novel.
   b. Mary began reading the novel.
   c. Mary began the novel.

Gerative Lexicon Theory handles such examples by the use of semantic selection (cf Pustejovsky, 1995) and canonical syntactic mapping rules, specifying how semantic types correspond to syntactic expressions. Here, the verb 'begin' is typed as taking an event description as its internal argument, begin (Ind, $\mathscr{E}$), which can be realized in one of the three syntactic forms shown. This illustrates how a generative system of type operations can account for polymorphic behavior of selection in the syntax.

Decomposition and Event Structure

The second major approach to the specification of lexical knowledge is that taken by decompositional theories. Most of this research has focused on the lexical specification for verbs, their arguments, and their syntactic behavior. Some recent work, however, has been done on noun semantics as well (Busa, 1996). In this section, we examine the motivations for lexical decomposition in linguistic theory, and the various proposals that have emerged on how to encode lexical knowledge as structured forms. We then relate this to the manner in which verbs refer to events, since this directly impacts the nature of the lexical decomposition structure.

Since Davidson (1967), events have played an increasingly important role in the determination of verb meaning. While early researchers on decompositional models (Dowty, 1979; McCawley, 1968) made no ontological commitments to events in the semantics for verbs, a new synthesis has emerged in recent years which attempts to model verb meanings as complex predicative structures with rich event structures (cf Hale and Keyser, 1993; Pustejovsky, 1991). This research has developed the idea that the meaning of a verb can be analyzed into a structured representation of the event that the verb

designates, and has furthermore contributed to the realization that verbs may have complex, internal event structures. Recent work has converged on the view that complex events are structured into an inner and an outer event, where the outer event is associated with causation and agency, and the inner event is associated with telicity (completion) and change of state. Under this view, a canonical accomplishment predicate as in 'John sliced the bread,' for example, can be represented as composed of an inner and an outer event. The inner event is the telic event in which the bread undergoes a change of state, and the outer event is the event in which John acts agentively (to do whatever is involved in the act of slicing). Since the outer event causes the inner one, it is associated lexically with causation.

Although there is a long tradition of analyzing causation as a relation between two events in the philosophical and psychological literature in contemporary models of natural language semantics this idea has only recently been adopted. For example, Carter (1976), one of the earlier researchers in this area, represents the meaning of the verb 'darken' as follows:

6. x CAUSE ((y BE DARK) CHANGE))

The predicate CAUSE is represented as a relation between a causer argument x and an inner expression involving a change of state in the argument y, although there is an intuition that the cause relation involves a causer and an event. Carter does not make this commitment explicitly. Levin and Rappaport (1995) follow a similar strategy, with a CAUSE predicate relating a causer argument and an inner expression involving a change of state in the argument y. The change of state is represented with the predicate BECOME:

7. wipe the floor clean:
   x CAUSE [y BECOME (AT) z] BY [x 'wipe' y]]
   x CAUSE [floor BECOME (AT) clean] BY [x 'wipe' floor]

The work of Levin and Rappaport, building on Jackendoff's Lexical Conceptual Structures, has been influential in articulating the internal structure of verb meanings (see Levin and Rappaport, 1995).

Jackendoff (1990) develops an extensive system of what he calls 'Conceptual Representations' which parallel the syntactic representations of sentences of natural language. These employ a set of canonical predicates including CAUSE, GO, TO, and ON, and canonical elements including Thing, Path, and Event. These approaches represent verb meaning by decomposing the predicate into more basic predicates. This work owes obvious debt to the innovative work within generative semantics, as illustrated by McCawley's (1968), analysis of the verb 'kill.' Recent versions of lexical representations inspired by generative semantics can be seen in the Lexical Relational Structures of Hale and Keyser 1993, where syntactic tree structures are employed to capture the same elements of causation and change of state as in the representations of Carter, Levin and Rapoport, Jackendoff, and Dowty.

Pustejovsky (1988, 1991) extends the decompositional approach presented in Dowty (1979) by explicitly reifying the events and subevents in the predicative expressions. Unlike Dowty's treatment of lexical semantics, where the decompositional calculus builds on prepositional or predicative units (as previously discussed), a 'syntax of event structure' makes explicit reference to quantified events as part of the word meaning. Pustejovsky further introduces a tree structure to represent the temporal ordering and dominance constraints on an event and its subevents. For example, a predicate such as 'build' is associated with a complex event such as that shown in (8):

8. $[_{\text{transition}}[e_1\text{: PROCESS}][e_2\text{: STATE}]]$

The process consists of the building activity itself, while the state represents the result of there being the object built. Grimshaw (1990) adopts this theory in her work on argument structure, where complex events such as 'break' are given a similar representation. In such structures, the process consists of what x does to cause the breaking, and the state is the resultant state of the broken item. The process corresponds to the outer causing event as discussed, and the state corresponds in part to the inner change of state event. Both Pustejovsky and Grimshaw differ from the authors above in assuming a specific level of representation for event structure, distinct from the representation of other lexical properties. Furthermore, they follow Higginbotham (1985) in adopting an explicit reference to the event place in the verbal semantics.

Qualia Structure

Thus far, we have focused on the lexical information associated with verb entries. All of the major categories, however, are encoded with syntactic and semantic feature structures that determine their constructional behavior and subsequent meaning at logical form. How this is accomplished, of course, varies from theory to theory.

In Generative Lexicon Theory, it is assumed that word meaning is structured on the basis of four generative factors, or 'qualia roles,' that capture how humans understand objects and relations in the world and provide the minimal explanation for the linguistic behavior of lexical items (these are inspired in large part by Moravcsik's (1975, 1990) interpretation of Aristotelian *aitia*).

formal: the basic category that distinguishes the object within a larger domain;
constitutive: the relation between an object and its constituent parts;
telic: its purpose and function;
argentive: factors involved in the object's origin or 'coming into being.'

Qualia structure is at the core of the generative properties of the lexicon, since it provides a general strategy for creating new types. For example, consider the properties of nouns such as 'rock' and 'chair.' These nouns can be distinguished on the basis of semantic criteria which classify them in terms of general categories such as natural_kind, artifact_object. Although very useful, this is not sufficient to discriminate semantic types in a way that also accounts for their grammatical behavior. A crucial distinction between 'rock' and 'chair' concerns the properties which differentiate natural_kinds from 'artifacts': functionality plays a crucial role in the process of individuation of artifacts, but not of natural kinds. This is reflected in grammatical behavior, whereby 'a good chair,' or 'enjoy the chair' are well-formed expressions reflecting the specific purpose for

which an artifact is designed, but 'good rock' or 'enjoy a rock' are semantically ill-formed since for 'rock' the functionality (i.e., TELIC) is undefined. Exceptions exist when new concepts are referred to, such as when the object is construed relative to a specific activity, such as in 'The climber enjoyed that rock'; 'rock' itself takes on a new meaning, by virtue of having telicity associated with it, and this is accomplished by integration with the semantics of the subject NP. Although 'chair' and 'rock' are both physical_object, they differ in their mode of coming into being (i.e., AGENTIVE): artifacts are man-made, 'rocks' develop in nature. Similarly, a concept such as 'food' or 'cookie' has a physical manifestation or denotation, but also a functional grounding, pertaining to the relation of 'eating.' These apparently contradictory aspects of a category are orthogonally represented by the qualia structure for that concept, which provides a coherent structuring for different dimensions of meaning.

For relations, the qualia act in a similar capacity to thematic relations, but where the individual qualia are possibly associated with entire event descriptions, and not just individuals. For discussion, see Pustejovsky (1995).

Consequence of Lexical Design

Considering the potential range of information that can be represented lexically results in a reconceptualization of what a lexicon is, so that the very design of the grammar is significantly impacted. Furthermore, our current understanding of psychological and computational properties of language processing suggests that the resources available for lexical storage and access are considerably higher than originally imagined by early grammatical theorists. The consequence is that, what had originally been accomplished in syntax, because of the combinatoric properties inherent in production rules, can be handled by the lexicon itself. The various approaches to lexical encoding can be analyzed in terms of two parameters.

1. Precompiling the information into lexical items forms;
2. Computing or generating new forms or senses during the compositional process.

Typically, idioms are presented as examples of precompiled lexical entries. But some theories have adopted this idea as fundamental for the entire compositional operation. The best example of this is CCG (Steedman, 1997). CCG has recently been articulated in enough detail to handle most of the major linguistic phenomena using a library of precompiled lexical types, together with the combinatoric rules of categorical syntax. If the grammar utilizes representations with such nonlocal dependencies, then there must be additional mechanisms for unifying these representations; these are provided in the form of function composition rules and lexical rules (Schabes et al., 1988).

Lexical rules have been invoked in HPSG, as well, to explain the relationship between the various senses for lexical items, from grinding and packaging operations (such as that relating the animal and food senses of 'chicken' and 'lamb,' to the relation between logically polysemous items, such as 'book' information and physical object), and 'lecture' (information and event) (cf Copestake and Briscoe, 1992). In Generative Lexicon such relations are explicitly represented in context (cf Johnston, 1995). It is very likely, however, that language makes use of both types of devices, namely complex types such as dot objects, as well as the application of lexical rules. Regardless, both types of devices must be seriously constrained by the grammar in order not to overgenerate unwanted forms and interpretations.

Considered independently of the issue of precompiled vs generated forms and senses, there is no question that the mental lexicon is large, containing arguably up to 400 000 lexical entries. This is based on fairly conservative estimates of speaker competence with active and passive vocabularies. For example, an average speaker lexicon might contain at least 5000 distinct verbs, 30 000 distinct nominal forms, and over 5000 adjectives. Combine this with an additional 10 000 compound forms and at least 300 000 distinct proper names. Obviously, the psychological (and hence computational) demands of these classes are quite distinct. There are two dimensions that can help us distinguish these classes: (1) the degree of combinatoric (functional) complexity of the lexical item; and (2) whether the lexical item is part of active or passive lexical knowledge. Most closed class items, for example, are functionally complex, as are many open class verbs and relational nouns. The majority of the open class items will also involve a fair amount of information regarding combinatoric possibilities. The class of names, however, is unique in that, although it is by far the largest class of lexical items, it is the least demanding in terms of computational resources.

In conclusion we see that the lexicon is neither a mere listing of morphemes in the language, nor a database of items passively waiting in the service of grammatical processes. Rather, the lexicon is a dynamic and active system of grammar, incorporating as well as dictating essential components of syntactic and semantic composition and interpretation.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser—Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Liaison and Consultation Psychiatry

Abstract

This article outlines historical and conceptual aspects, as well as the scope of consultation–liaison psychiatric services in primary and hospital care settings, and in the care of residents with psychiatric disorders in nursing homes. Community studies show that members of the general population who suffer from a physical illness are at increased risk of suffering additionally from a psychiatric disorder. These figures increase in patients seeking help from primary care doctors, and are highest in patients treated in medical–surgical wards of general hospitals. Patients in general hospitals show high rates of comorbid psychiatric disorders, especially organic psychoses, e.g., delirium in dementia, alcohol and other addictions, somatoform and affective disorders including adjustment disorders. Studies show a significant association between psychiatric comorbidity and more complicated illness courses, with longer lengths of stay in hospital and more frequent readmissions, leading to poorer outcomes and increased costs in the treatment of such patients. Inpatients suffering from psychiatric comorbidity have longer lengths of hospital stay than patients with the same severity of the underlying or concomitant physical disease, who are not in addition psychiatrically ill. The high rates of psychiatric comorbidity in physically ill general-hospital inpatients, primary care patients, and nursing home residents are the focus of consultation–liaison psychiatry. Psychiatric care leads to improved management of patients with medical–psychiatric comorbidity, and a reduction of unnecessary costs inflicted on health care systems through underdiagnosis and undertreatment of psychiatric comorbidity. This holds true especially for patients presenting with medically unexplained symptoms not due to organic disease. In order to improve course and outcome of patients with medical–psychiatric comorbidity, psychiatrists have to be involved in their care, as in most of the Western industrialized countries this became possible by the integration of psychiatric departments in general hospitals. General hospitals present an important pathway to specialist psychiatric care for such patients, who will often be seen for the first time by a psychiatrist after having been admitted for a physical disease or for physical symptoms that cannot be explained by an underlying physical disease. Educational and training developments should lead to more elaborate consultation–liaison psychiatric curricula within specialist psychiatric training. Far more, training programs are needed to increase nonpsychiatric physicians' and medical staffs' knowledge of and experience in diagnosis and treatment of psychiatric issues, in order to improve care of patients with somatopsychic disorders in primary and hospital care settings. The development of guidelines for consultation–liaison psychiatric practice and the emergence of joint psychiatric and medical approaches in the care of patients with physical diseases and psychiatric comorbidity, especially within primary care, are expected in years to come.

Consultation–liaison psychiatry delineates the work of psychiatrists with patients who are in medical treatment primarily for somatic reasons in nonpsychiatric departments of a general hospital, or in outpatient care of a nonpsychiatric physician. More specifically, consultation psychiatry describes a practice where psychiatrists see patients treated by other nonpsychiatric physicians only when called upon to give advice about diagnostic and treatment issues to consultees, who in turn are supposed to follow through on these recommendations in the treatment of their patients. In liaison psychiatry, however, psychiatrists are involved more directly in the treatment of physically ill patients with psychiatric comorbidity, assuming more responsibility in joint patient care (e.g., having the prerogative of seeing patients admitted to a pain clinic or an oncological ward without being specifically endorsed to do so in every given case), as well as starting and following through psychiatric or psychotherapeutic treatment. As in everyday clinical care, boundaries between consultation and liaison approaches are not clear-cut, a worldwide consensus has developed to use the phrase consultation–liaison psychiatry (or c–l psychiatry), with the notable exception of the UK, where liaison psychiatry is the only term used for both kinds of approaches. In the United States, c–l psychiatry has been approved by the American Board of Medical Specialties as a subspecialty of psychiatry, referred to as 'Psychosomatic Medicine' (Angelino and Lyketsos, 2011).

Psychiatric Comorbidity in Physically Ill Patients

The need for c–l psychiatric services stems from the high comorbidity of psychiatric illnesses in patients suffering from physical diseases.

Psychiatric Comorbidity in the General Hospital

It is estimated that between 30 and 50% of physically ill patients in general hospitals show comorbid psychiatric disorders, especially organic psychoses (*ICD-10* F0), psychological and behavioral disturbances due to psychotropic substances (*ICD-10* F1), and acute stress reactions (*ICD-10* F4), with percentages of these diagnoses ranging as high as 16, 8 and 10% in medical, and 17, 8 and 13% in surgical patients, respectively (Diefenbacher et al., 2011). Special patient populations – such as those in organ transplantation programs, intensive care units, or oncological patients – show an even higher psychiatric comorbidity. Patients with head and neck cancer, for instance, have been reported to have persistent

depression up to 40% (Hodgkiss and Mascarenhas, 2012). The presence of any psychiatric comorbidity does not always call for immediate psychological treatment at the same time as the underlying or concomitant acute physical disease, which has led to hospital admission, is being cared for by physicians or surgeons. Nevertheless, conservative estimates point to a figure of some 10% of general-hospital inpatients who should receive psychiatric care alongside somatic care during the index episode.

While the evaluation of patients committed to Accident and Emergency Departments after attempting to harm themselves is an important task for psychiatrists, and will often be performed by c–l services, their care is only one part of a larger picture of care for patients suffering from medical–psychiatric comorbidity, with the latter impacting negatively on course and outcome of the former. A prerequisite for psychiatric services to achieve an impact on this group of patients is the integration of psychiatry into general hospitals. Thus, in the United States, where the foundation of psychiatric departments as integrated parts of general hospitals started as early as the 1920s, c–l psychiatry has a long tradition, whereas in the Federal Republic of Germany, for instance, where state mental hospitals have given way to general hospital psychiatric departments only since the end of the 1970s, c–l psychiatry started to gain shape only toward the end of the twentieth century. Overall, international interest in c–l psychiatry increased outside the United States during the 1980s and 1990s with special emphasis in the UK, the Netherlands, Australia, and New Zealand, where c–l psychiatric sections were founded within national psychiatric organizations. More recently, in other European countries, e.g., Switzerland, and on a European level, as represented by the European Association of Psychiatry, sections for c–l psychiatry have been founded (Lobo et al., 2007; Georgescu et al., 2009).

The history of c–l psychiatry shows that in order to achieve acceptance of psychiatric care for patients with medical–psychiatric comorbidity, regular availability of psychiatrists in general hospitals is very helpful, as this provides the opportunity to demonstrate the added value of psychiatric diagnosis and treatment to other medical disciplines in the care of comorbid patients.

Psychiatric Comorbidity in the Primary Care Sector

While c–l psychiatry developed primarily in the general hospital setting, there was growing emphasis worldwide on diagnosis and treatment of psychiatric comorbidity of patients in the primary care sector toward the end of the twentieth century. Results from the *National Institute of Mental Health Epidemiological Catchment Area Program* show that about 16% of the community-dwelling adult population fulfills criteria for at least one psychiatric disorder. This figure increases to at least 21–26% of primary care patients. Up to 90% of patients with depression and anxiety disorders are estimated to be treated solely in primary care (Archer et al., 2012). In most cases, these patients present with physical symptoms that are not caused by physical disease (*see* Somatoform Disorders). The proportion of undetected and untreated psychiatric (co)morbidity in this patient group is high (Goldberg, 2010).

Psychiatric Morbidity in Nursing Homes

The percentage of the population older than 65 years of age is increasing. It is estimated that 20–50% of these people will eventually live in nursing homes. The very high prevalence of psychiatric-related illness among those in nursing homes is documented in a number of studies, showing that up to 70% of nursing home residents may meet diagnostic criteria for dementia, and 90% may have at least one form of behavioral disturbance, such as agitation, delusions, or depression. Depression is largely undetected and undertreated in this population, despite the fact that the majority of cases treated, e.g., with antidepressants, will recover from a depressive episode. Only recently, there has been growing awareness that people with learning disability show a significantly higher percentage of psychiatric comorbidity than the average population. While attempts are made to achieve a close to normal living situation for a large part of this clientele, people with severe mental retardation – which is often complicated not only by psychiatric comorbidity, but also by other physical diseases such as epilepsy – will receive adequate care mostly in nursing home settings (Martinez-Leal et al., 2011).

In sum, there has been increasing awareness of hidden mental comorbidity in the general hospital, primary care, and nursing home sectors and of the need for specialist psychiatric treatment in a significant percentage of patients or residents being treated or living in those settings.

Effects of Psychiatric Comorbidity in Physically Ill Patients

Studies show a significant association between psychiatric comorbidity and more complicated illness courses, both for patients in the primary care sector and for general-hospital inpatients. Patients with somatization disorder use nine times the health care services of the general population, panic disorder patients have 10 times the number of visits to hospital emergency rooms than nonanxious patients, and 70% will see more than 10 physicians before an accurate diagnosis is made. Medically ill patients with depression have a poorer prognosis than nondepressed patients with equal somatic morbidity. For example, postmyocardial infarction patients with depression are at significantly greater risk of death over a period of 6 months following the infarction, and depressed stroke patients show poorer results in rehabilitation programs with more persistent disability than nondepressed stroke patients. It has been shown that a small percentage of patients are responsible for the use of a major portion of health care, with, for example, 10% of patients of a large health maintenance organization in the United States consuming approximately one-third of all primary care visits, 52% of all speciality visits, and 40% of in-hospital days. Fifty percent of those high utilizers of health care showed some form of psychiatric comorbidity, e.g., 20.2% somatization disorder, 33.6% generalized anxiety disorder or panic disorder, and 40% major depression and dysthymia. The finding of high psychosomatic morbidity in frequent health care utilizers was confirmed in several studies (e.g., Ferrari et al., 2008).

In general-hospital inpatients, it has been shown that medically ill patients with psychiatric comorbidity show longer lengths of stay in hospitals, more frequent readmissions, and

an overall increase in costs for treatment as compared to patients without psychiatric comorbidity. Adjustment for other factors associated with longer length of stay and rehospitalizations, such as severity of underlying medical disease, did not reduce the significance of the negative impact exerted by psychiatric comorbidity (Diefenbacher, 2000). The elderly are exposed to special risks, with about 10% of elderly patients admitted to a general hospital suffering from delirium. About 30% of elderly medical inpatients have dementia, which makes more complex management necessary, with problems arising from, for example, diminished compliance with medication, and in following through with rehabilitation programs (Teodorczuk et al., 2010). With regard to limited financial health care resources, this problem is more and more recognized in the medical setting and models of care have been developed, which include improvement of prevention, early detection and, management of psychosomatic comorbidity in the elderly. These models are often nurse-led and involve psychiatric support by multiprofessional c–l teams in stepped care approaches (Gurlit et al., 2013).

The Practice of Consultation and Liaison Psychiatry

The scope of c–l psychiatric services spans primary and hospital care settings, the care of elderly residents in nursing homes, and of clients with learning disability and accompanying psychiatric disorders.

C–L Psychiatric Services in the General Hospital

Despite the high percentage of psychiatric comorbidity in the general hospital, referrals to psychiatric c–l services amount at most to only a small number of physically ill inpatients, approaching an average number of 1–2% of general-hospital inpatients worldwide. Usually, the majority of patients is referred by internal medicine departments, with a large percentage being older than 65 years of age. Despite all differences in service delivery that are due to local necessities in the provision of care for given populations, c–l psychiatrists most often diagnose delirious states and other disorders of cognition, followed by depressive syndromes and adjustment disorders, fitting well to the above mentioned prevalence figures of psychiatric comorbidity in general-hospital patients. In contrast, despite their obvious frequency, patients with alcohol-use disorders are referred much less by their treating physicians. The low rate of referrals to psychiatric c–l services has led to the assumption that nonpsychiatric physicians do not recognize psychiatric disorders sufficiently, or, if they do, do not think of psychiatric interventions as being helpful to their patients. The concept of liaison psychiatry properly takes its vantage point from this discrepancy: other than the usual psychiatric consultation with its mainly emergency psychiatric character that by default is only able to care for the tip of the iceberg of psychiatric comorbidity, i.e., patients having passed the filter of recognition of a nonpsychiatric physician. Liaison psychiatric approaches aim at the denominator of psychiatric comorbidity, triggering specialist psychiatric care, e.g., by screening patients on hospital admission, or identifying problem behavior in joint rounds with nonpsychiatric physicians. More recent c–l developments show the advantages of multiprofessional c–l teams including psychiatrists, as well as mental health nurses (MHN), social workers, and clinical psychologists. In these models, MHN play a leading role not only in caring for medically ill patients with psychiatric comorbidity, but also in providing a role model and peer-to-peer training for medical staff (Burian et al., 2014; Sharrock et al., 2008). Thus, liaison psychiatric approaches try to go well beyond the 'firefighter function' of typical psychiatric consultation, aiming at changing referral patterns of nonpsychiatric departments, e.g., enabling physicians to deal with and/or prevent the development of delirious states, or increase referral rates of depressed patients or patients with alcohol-use disorders by demonstrating the efficacy of even time-limited psychiatric interventions (RCPhys and RCPsych, 2003).

Both in consultation and, to a somewhat lesser extent, in liaison psychiatric approaches, psychiatrists have to be aware of the stages a psychiatric consultation will typically go through. In the initial phase and due to uncertainty about how to deal with a patient, the consultant's referral diagnosis might be rather imprecise. In such cases, it must be the task of the c–l psychiatrist to help in working out what is in fact the problem. The ensuing intervention must then be, other than in a typical psychiatric office situation, directed not only toward the patients, but also take into consideration the whole system, including the ward doctor, nurses, and relatives. Otherwise, c–l psychiatric interventions, when performed in isolation and/or out of context, might be unsuccessful (Diefenbacher, 2000).

C–L Psychiatric Services in Primary Care and in Nursing Homes

Along with the growing interest in psychiatric (co)morbidity in primary care patients and nursing home residents, international c–l psychiatry shows a remarkable shift from the general hospital setting to collaborative care practices in the primary care setting, and, though still in its beginnings, to liaison psychiatric services with nursing home populations. For primary care settings, studies show that inclusion of a nurse-therapist and a psychiatrist in primary care treatment teams, e.g., on the basis of regularly performed nurse-based visits as well as consultations by a psychiatrist in a stepwise approach, leads to a marked improvement in the symptoms of patients with somatoform disorders or depression compared to provision of services by primary care physicians alone (van der Feltz-Cornelis et al., 2010). For nursing home populations, the need to consider psychopharmacological as well as, and more importantly, psychosocial interventions such as supportive environmental therapies, recreational therapies, and so on, in combined treatment plans tailored to specific residents and specific nursing home settings, stress the need for psychiatrists to oversee the implementation of such integrated approaches. Hence, liaison models with more intense involvement of psychiatrists working with other nonpsychiatric physicians and psychologists, as well as administrative and nursing staff in addition to care for residents and their relatives will be developed in the near future. The latter holds especially true for people with learning disability, as diagnostic and treatment approaches in this clientele will require special expertise not necessarily familiar to primary care physicians, or even psychiatrists themselves (Dagnan, 2007). Especially in patients

who are not able to communicate verbally, unexplained behavioral changes or challenging behavior may reflect an underlying psychiatric disorder, which in turn may be treatable, as in the case of hostile behavior in demented patients with dysphoric depression that may well respond to pharmacological treatment with, for example, selective serotonin reuptake inhibitors. C–l psychiatrists working in such settings are ideally placed to teach nursing staff and primary care physicians that expert assessment of behavioral and psychological symptoms in nonverbal patients may lead to more specific management and hence better patient care. Thus a patient with dementia whose delusional experiences lead to bizarre behavior should be treated differently from a demented patient who suffers from pain, or a depressed nonverbal patient who refuses aggressively to accept food. Of note, in the nursing home setting, but also due to demographic changes with a further increase of frail elderly patients in the general hospital, geriatricians also play an important and ever increasing part in the care for this population, and c–l psychiatrists should seek to establish joint approaches with geriatric services, when available.

Despite the increasing interest in models of collaborative care in the outpatient, as well as nursing home sectors, it has to be kept in mind, that, at least at this point in time, many patients with somatopsychic comorbidity are seen for the first time at all by a psychiatric specialist only after having been admitted to a general hospital. Thus, psychiatrists as well as planners of health services will have to bear in mind that general hospitals may be referred to as 'virtual psychiatric sectors.' This underlines the importance of the general hospital as a pathway to specialist psychiatric care.

Evaluation of C–L Psychiatric Interventions

Psychiatric care leads to improved management of medically ill patients with psychiatric comorbidity. This is the rationale of the practice of c–l psychiatry, whose benefits can be demonstrated within a value matrix, taking into account treatment outcomes in medically ill patients with psychiatric comorbidity, as well as economic savings by adding specialist psychiatric treatment to standard medical treatment. Cost-benefit issues of consultation psychiatry service delivery have been demonstrated initially in general-hospital inpatients, with primarily US studies showing a trend to reduced length of hospital stay with corresponding reductions in cost of treatment in medical patients after a psychiatric liaison service was inaugurated, compared with control groups without such an intervention program. However, as other studies failed to show such an effect, the overall conclusion was that this research approach had to be judged as inconclusive in the face of a sharp decrease in lengths of hospital stays worldwide due to secular trends in shifting the provision of health care into the outpatient sector, and the inauguration of diagnosis related groups (DRG)-based payment systems, in order to reduce the escalation of overall health care costs (Diefenbacher and Strain, 2002). Consequently, research on the efficacy of psychiatric intervention strategies in patients with psychiatric (co)morbidity in the primary care sector has increased. Studies showed that integrated c–l psychiatric approaches, but not those that only offered just screening strategies to identify patients with psychiatric disorders, have led to improved outcomes in patient care. In the inpatient setting, models of integrated medical and psychiatric care also are being proposed. It could be shown that multiprofessional liaison approaches lead to reduced incidence and early detection of delirium especially in older patients in the general hospital. These interventions were mostly nurse-based and train medical staff on internal-surgical wards to manage patients with elevated risk for delirium. Such approaches may lead to better outcomes and prevention of prolonged hospital treatment due to complications of delirium (Leentjens et al., 2011).

Even in outpatient primary care settings, best results are achieved with multiprofessional and integrated care approaches that make all professionals involved in patients therapy work collaboratively together. According to structured treatment plans and follow-up schedules, trained nurses who apply psychosocial interventions to the patients play a major role. Psychiatrists are involved as specialists who supervise the treatment process and apply patient visits in a stepped care plan only to those who do not get better in the baseline treatment provided by patient's general practitioners (GPs) and trained nurses. Collaborative care models have been developed for depression, anxiety, and somatoform disorders. These approaches show benefits for patients' well-being, and also cost-efficacy (Archer et al., 2012; Ekers et al., 2013). Far more, collaborative care models also have an impact on the somatic morbidity. For instance, heart failure patients who were treated for depression in a collaborative care approach had significantly less adverse coronary events than patients with the same comorbidity who were treated in usual care (Davidson et al., 2010).

Future Developments in C–L Psychiatry

Future developments will see an increased emphasis on the education of both psychiatrists and primary care practitioners in collaborating in the treatment of medically and psychiatrically ill patients, in the development of models of integrated care, and the need to develop and implement guidelines and standards of care in quality assurance programs for patients suffering from somatic and psychiatric disorders alike. Collaborative care models in primary care as well as multiprofessional nurse-based services in general-hospital inpatients settings that have been proven as successful and cost saving, should now be rolled out in daily clinical practice.

Education

The education of physicians working at the interface of medical–surgical and psychiatric medicine has to be twofold. Psychiatrists have to learn how to treat medically ill patients with psychiatric comorbidity. Psychiatric training cannot remain restricted to gaining experience predominantly with patients with schizophrenia or manic-depressive illness, but has to take into account the needs of patients suffering from medical illnesses and comorbid psychiatric illness, for example, depressive patients suffering from cardiac disease or stroke or kidney failure, who require somatic as well as psychological treatment. To achieve this goal, c–l psychiatric curricula are

being developed within specialist psychiatric training, e.g., in Europe and the United States. Psychiatrists will have to become proficient in mastering diagnostic and treatment problems arising from somatopsychic comorbidity, e.g., address problems of diagnosing depressive disorders in the medically ill, and adjusting psychological as well as psychopharmacological treatment issues for patients suffering from both medical and psychiatric disorders.

On the other hand, c–l psychiatrists will have to add to the education and training of primary care physicians and medical staff. Training programs have been developed to broaden nonpsychiatric physicians' and nurses' knowledge of and experience in diagnosis, referral, and treatment of patients with psychiatric (co)morbidity, in order to improve the care of patients with somatopsychic disorders in primary and hospital care settings. Psychiatrists, as well as nonpsychiatric physicians, will have to adopt behavioral medicine treatment strategies for patients with, for example, somatization disorders and chronic pain syndromes, and, most importantly, will have to learn treatment strategies other than psychotropic drug prescribing strategies such as cognitive behavioral treatment for patients with adjustment disorders, anxiety disorders, and the milder depressive disorders (the so-called subthreshold disorders), as these disorders make up the bulk of psychiatric comorbidity treated in the primary care sector. Psychopharmacological treatment has to be applied with caution. Recent studies showed that their effect on depressive and anxious symptoms is depending on symptom severity at baseline. Mild and moderate depressed patients benefit from placebo as good as from medication. These findings indicate that non-pharmacological interventions can be applied, so patients will be not exposed to the risk of adverse drug reactions (Fournier et al., 2009).

Guidelines and Quality Assurance

As the awareness for an improved psychological care of medical and surgical patients increased toward the end of the twentieth century, one step has been the development of guidelines in order to define standards of care. In the UK, conjoint working parties of physicians, surgeons, and psychiatrists (e.g., Royal Colleges of Physicians, and Psychiatrists, 2003) published documents with practical suggestions regarding methods of identifying potentially harmful psychological components of patients' illnesses, and recommendations for the provision of care as well as for referral for psychiatric or psychological help when appropriate. As only a minority of patients will need psychiatric care in addition to medical–surgical treatment, these guidelines underline that normally physicians and surgeons should be able to make some assessment of psychological factors as integrated part of their daily routine. The guidelines propose simple screening mechanisms in order to improve detection of psychological disorders in the general hospital, for example, the *CAGE Questionnaire* for screening for alcohol misuse or the *Confusion Assessment Method (CAM)* for the early detection of delirium, to be used by medical–surgical physicians and nursing staff alike. Overall, the implementation of guidelines is thought to help in a number of areas, such as in reducing the number of (unnecessary) investigations performed for physical symptoms that result from underlying stress, as, for example, in patients with somatization, help in relieving symptoms of stress and improving the quality of life of patients with serious physical illness.

It is assumed that the implementation of guidelines within quality assurance programs will lead eventually to improved patient care, although guidelines alone do not work unless there is sufficient training and a clear protocol with scheduled follow-ups (NICE, 2010; Young and George, 2003). However, measures against which to gauge c–l psychiatric interventions have yet to be established. Given the low referral rate for psychiatric consultation as compared with the high prevalence of medical–psychiatric comorbidity, and the need for specific psychiatric treatment in general-hospital inpatients, as a first step to improving care, the C–l Psychiatric Section of the Royal Australian and New Zealand College of Psychiatrists proposes to define the benchmark for psychiatric referrals to be 5% of all admissions to medical–surgical wards of a general hospital. If this percentage is not reached, an audit should be performed to establish whether there are identifiable reasons for not providing psychiatric support in an adequate number of patients in medical–surgical departments of a given general hospital.

Research in C–L Psychiatry

Basic requirement for research in c–l psychiatry is the identification of high-risk patient groups, such as those suffering from a significant amount of psychiatric comorbidity. Failure to identify such high-risk groups, along with the overstated assumption that just one psychiatric consultation might lead to improved patient outcomes, may have been the basis of the ambiguous results of general-hospital inpatient intervention studies performed in the United States in the 1980s. C–l research in the primary care setting, on the other hand, has demonstrated that restriction to a high-risk group with identifiable psychiatric comorbidity, e.g., high utilizers in primary care suffering from a psychiatric disorder, such as somatoform disorder, may demonstrate that a psychiatric intervention can lead to improved patient outcomes, if the intervention is intense enough. There is good evidence that collaborative care models as described above reduce health care utilization in primary care patients treated for depression and somatoform disorders (van der Feltz-Cornelis et al., 2010).

Problems that need to be solved in order to improve care of patients with medical–psychiatric comorbidity are:

1. To develop a more precise description of the phenomenology of psychiatric illnesses comorbid with particular physical illnesses, e.g., as in the case of the differential diagnosis of demoralization versus depression in patients severe and fatal medical disorders like cancer (Price and Hotopf, 2012).
2. To further study efficacy and effectiveness of psychotherapeutic and psychopharmacological treatment strategies in patients with medical–psychiatric comorbidity. Meta-analyses point out that multiprofessional psychiatric treatment, especially when delivered in collaboration with patients attending somatic doctor or GP, is as effective in depressive patients with medical comorbidity as in those without (Archer et al., 2012).

3. To further study service delivery for migrant patients and ethnic minorities. Globalization demands adaptation of care models to the specific needs of these patients. Migration is known to be a risk factor for psychiatric morbidity and migrants often face barriers for access to health care and mental health care. Far more, the misinterpretation of culturally different presentations of mental health problems, e.g., bodily and pain symptoms as signs for underlying depression, may lead to underdiagnosis of psychiatric disorders in such patients in primary care or general hospitals.
4. To develop new models of conjoint somatic and psychological care within general-hospital inpatient settings that must take steps to be prepared for an increasing number of frail elderly patients who suffer from dementia and will react with behavioral disturbances or even the development of delirium due to medical interventions and/or the, at present, not overtly supportive environment they are put into without having time to adapt themselves (cf Section Integration of Medical and Psychiatric Services) (Bartels and Naslund, 2013).

The effectiveness of different models of care for medical patients with psychiatric comorbidity with regard to different outcome measures such as clinical improvement, quality of life, or cost effectiveness, will require further investigation, especially in inpatient settings for different patient populations, e.g., acute versus chronic care patients, with regard to differential effects of more traditional consultation or liaison approaches versus collaborative care as described above.

Integration of Medical and Psychiatric Services

A model for integrated medical and psychiatric treatment programs within the general hospital were the so-called medical–psychiatric units that were developed primarily in the United States during the 1990s, but they remained controversial in terms of cost-efficacy and did not achieve a significant impact within the departments of somatic medicine, as they were mostly integrated within psychiatric departments. But as the need for specialized care for high-risk patients, for example, delirious patients and somatically ill patients with dementia and behavioral disturbances who cannot be managed on medical–surgical wards, or suicidal patients in need of acute medical treatment that cannot be provided on a psychiatric ward, is increasing, there are attempts to put such ideas of conjoint care on a broader basis. It has been proposed recently to move on and develop the so-called Complexity Intervention Units, beyond departmental boundaries and outside psychiatric departments (Kathol et al., 2009). Such conjoint models of care in the inpatient setting should lead to improved patient outcome while saving costs, as compared with traditional models of sequential care with referrals from psychiatric to medical departments and vice versa. Apart from the development of pharmacological treatment strategies to prevent the development of postoperative delirium that is increasingly advocated (Teslyar et al., 2013), recent developments favor mobile approaches in which multiprofessional and mostly nurse-based teams support the attending teams on the somatic wards in the management of complex patients with high degrees of medical–psychiatric comorbidity, such as 'delirium teams' or 'self-harm teams.' These teams shall also take responsibility for the continuity of care once the patients are discharged from hospital back into their community.

Epilogue

Readers interested in widening their knowledge of the topics dealt with in this article are referred to textbooks of consultation–liaison psychiatry and psychosomatic medicine (e.g., Levenson, 2011; Creed et al., 2011). Journals like 'Psychosomatics,' 'General Hospital Society,' and the 'Journal of Psychosomatic Research' are dedicated to the field of medical–psychiatric comorbidity. The homepages of national and international psychiatric and psychosomatic associations are frequently updated to deliver information on congresses, symposia, and training workshops in c–l psychiatry and psychosomatic medicine (www.europsy.net, www.eapm.eu.com, www.apm.org).

Abstract

Liberal Christianity arose in the seventeenth and eighteenth centuries in response to the Enlightenment and modernism. The progressive force of liberal Christianity concerned itself with rationalism and individual liberty, in response to authoritarian fundamentalism and antimodernism. While earlier treatments argued that liberal Christianity was unsustainable, contemporary developments have shown that it remains a major feature of twenty-first century Christianity and that it enjoys considerable influence throughout the West.

'Liberal' is the designation given to a broad trajectory in Christianity by sympathizers and critics alike. In some of its manifestations it is also referred to as 'modernism.' Both terms draw attention to a defining characteristic: a dissatisfaction with earlier forms of religion and a concern to replace them with less restrictive alternatives more open to accommodating secular society. While it has rarely led to the establishment of new churches, liberalism has had a significant impact within all the mainline Christian denominations in the West.

Understood in this broad sense, liberal Christianity can be seen to date back even before the Renaissance to the fifteenth century, when the term 'modern' was first invoked in relation to reforming movements in theology and spirituality like the 'Via Moderna' and the 'Devotio Moderna.' Since then Western Christianity has been challenged repeatedly by individuals and movements who have championed the freedom of the individual Christian from the authority of institutional religion. Yet it is in the modern period that liberal Christianity has become most prominent and has played its most important role in shaping modernity itself.

By the end of the twentieth century, something of a consensus had developed among sociologists of religion that liberal Christianity was in inexorable decline. This consensus coincided with a period when theological liberalism had fallen out of fashion; however, this view has been challenged in the new millennium as conservative Christianity has been shown to be less ascendant than was assumed, and many liberal religious groups have seen considerable growth or stability (Sherkat, 2014). The dismissive view of liberal Christianity results from three critical oversights: (1) it overlooks the internal variety of liberal Christianity; (2) it ignores evidence of its continuing vitality on the ground; and (3) it fails to recognize that liberal Christianity remains well adapted to many of the socioeconomic formations and cultural trends of the modern world.

Varieties of Liberalism

Rationalist

One of the most important ways in which liberal Christianity is implicated with the rise of modernity is through its central role in the Enlightenment of the mid-seventeenth to mid-eighteenth centuries. In their different ways, such figures as the Deists, Thomas Jefferson, Tom Paine, Rene Descartes, John Locke, and Immanuel Kant were all concerned with the liberal reform of religion. They helped shape a liberal Christianity, which was characterized by (1) hostility to 'traditional' religion, conceived as superstitious, heteronomous, and divisive; (2) confidence in human reason and the primacy of the sovereign individual; (3) activist optimism about the possibilities of human and social improvement; (4) belief in the harmonious unity of all true ('natural') religion; and (5) high valuation of freedom. Rationalist liberalism tended to be primarily an intellectual movement, though it was often related closely to political radicalism. At the institutional level, it gave rise to the Unitarian and Universalist churches, whose rejection of first the divinity of Jesus and later of deism could classify them as a new religious movement (Sherkat, 2014).

Romantic

While many sociologists identify liberal Christianity with its rationalist forms, there are other important varieties. By the late eighteenth century, for example, a Romantic liberalism had begun to exercise an important cultural and religious influence. In America, this was best represented by Transcendentalism, and in Germany by the theology of Friedrich Schleiermacher. Romantic liberalism inherited rationalist liberalism's belief that the individual rather than the institution was the locus of true religion ("my mind is my church," as Tom Paine had put it), but stressed the authority of feeling, imagination, experience, and self-consciousness rather than reason. This stress on the importance of individual experience of God has been carried through into the twentieth century in the work of theologians like Rudolf Bultmann and Paul Tillich.

Ethical and Social

Kant had located religious authority in moral reason. This 'ethicization' of the Christian religion was taken further in Germany by theologians like Albrecht Ritschl, Wilhelm Herrmann, and Adolf von Harnack, and in America by theologians like Horace Bushnell and Walter Rauschenbusch. The last of these, the leader of the Social Gospel movement, was responsible for interpreting Christianity as a force for social reform in industrial society.

Liberation and Feminist

In the twenty-first century, the influence of liberal Christianity continues to be felt in new reform movements within the churches and theology, most notably in some important varieties of Liberation theology (a product of Latin America) and Feminist Theology (a product of North America and Western Europe). In both, we find a characteristic emphasis on human liberation and the authority of experience, combined with a thoroughgoing criticism of existing structures of power and domination in both the churches and wider society, and a bias toward the oppressed and marginal. The importance of liberation theologies has been reinforced by current developments in the Catholic Church, particularly under Pope Francis.

The Development of Modern Liberalism

Liberalism has had the greatest impact within mainline Protestant churches, and has been particularly influential in countries where Protestantism has been dominant. Most commentators consider its heyday to have been from the mid-nineteenth century through the 1920s. Liberalism flourished because it was able to meet the new challenges posed by the forces of modernization. Its critical stance toward Christian tradition enabled it to assimilate the rise of historical method and its application to the Bible. Equally, its long-held belief in progress and the capacity of human reason to fathom the mysteries of God and the world helped it embrace the discoveries of modern science, including evolution. What is more, its libertarianism and individualism enabled it to support the interests of the new middle classes and to play a legitimating role in relation to democracy and the modern state. Far from being threatened by rapid modernization in the nineteenth century, liberal Christianity tended to view itself as the religious and moral engine of social progress. Nowhere was this truer than in the United States. In Catholic countries, the picture was very different. There, led by an increasingly defensive Rome, the church explicitly repudiated the errors of 'modernism' (which included political and religious liberalism), and allied itself with the forces of reaction. In 1907, Pope Pius X condemned those Catholic 'modernists' who had embraced aspects of theological liberalism, and introduced an antimodernist oath for the clergy which effectively ended all attempts to develop a liberal Catholicism. It was not until the Second Vatican Council of 1962–65 that a moderate liberalism gained official sanction. Since then there has been an explosion of liberal thought in the Catholic Church, despite Pope John Paul II's and Pope Benedict XVI's attempts to curb its influence. Indeed, the installation of Pope Francis marks a renewed liberalism in the Catholic Church. The work of theologians like Hans Kung, as well as the rise of Liberation Theology and Feminist Theology, has been particularly notable.

The twentieth century has brought unprecedented challenges for liberal Christianity. These include the rise of conservative evangelical and fundamentalist Christianity and, at the theological level, the rise of neoorthodoxy. At the same time, many elements of the liberal creed – including belief in progress, reason, 'humanity,' and the ideal of religious unity – have been shaken both inside and outside the churches. This together with shrinking attendance in the mainline Protestant churches most influenced by liberalism has led many commentators to conclude that it is in terminal decline. What this conclusion overlooks, however, is that the mainline denominations still account for the vast majority of Christians (especially if one includes the Catholic Church), and that many within these denominations (including the Catholic Church) continue to embrace some version of liberal Christianity. What is more, liberalism remains extremely well adapted to societies that show no real sign of diminishing their commitment to freedom, equality, democracy, and a liberal individualism reinforced by the institutions of a free-market economy.

Liberalism on the Ground

Dean Kelley's book *Why Conservative Churches Are Growing* (1972) captured a new mood in the sociology of religion. Where secularization theory had previously encouraged the conclusion that the more traditional and antimodern forms of religion would be those that would decline most rapidly, the growth of conservative and sectarian bodies alongside evidence of the decline of more liberal denominations led to a change of mind after the 1960s. In the late twentieth century, sociological theory was quickly mobilized to explain this change, and to reinforce the prediction of further liberal decline.

Much of the case for liberal decline focuses on the American example. It is clear from survey data in the United States, like the General Social Survey, that liberal Protestant denominations such as the Presbyterians, Episcopalians, and the United Church of Christ did indeed decline among younger generations, and this was also true for many moderate Protestant groups like the United Methodists, Lutherans, and Disciples of Christ. By contrast, more conservative denominations like the Southern Baptist Convention and the Seventh-day Adventists appeared to grow in numbers.

In contrast to the claims of supply-side 'rational choice' theorists (e.g., Iannaccone, Finke, and Stark), however, the decreasing proportion of Americans identifying with liberal and moderate Protestant churches was not accompanied by a surge in affiliation with antimodernist sectarian groups. Indeed, the largest sectarian denomination, the Southern Baptist Convention, is in decline, and other sectarian groups are stable, not growing (Sherkat, 2014). The Catholic Church remains stable in spite of its liberalism, and the growing Latino Catholic population may further spur its embrace of liberal Christianity. While critics of liberalism enjoy pointing to the growth of the Mormons, they remain a small denomination, which now has very low rates of retention among the young. Further, the Unitarian Universalists are enjoying considerable growth from switching – higher than that found among Mormons (Sherkat, 2014). Indeed, the primary reason for higher levels of decline in liberal and moderate denominations is that their members have lower fertility rates (Sherkat, 2014).

It is also necessary to exercise caution when relying on data relating to levels of denominational attendance and affiliation alone in assessing the state of liberal Christianity in the churches. The main problem with this method is that it is blind to complex patterns of belief and commitment within churches and denominations. For example, most mainline churches

today – both Catholic and Protestant – contain both liberals and conservatives within their congregations, and it is increasingly hard to label whole denominations 'liberal' or 'conservative.' What is more, there is some important evidence that even more conservative forms of Catholic and evangelical Christianity are increasingly permeable to the influence of liberalism. Thus, James Davison Hunter's extensive research among college-age Evangelicals in American uncovered evidence of an increasing liberalization of their belief, values, and practice (Hunter, 1987).

Ammerman (1997) who studied 23 representative congregations across the United States and surveyed almost 2000 individuals discovered that respondents fell into three categories: liberal or 'Golden Rule' Christians (51%), evangelicals (29%), and social activists (19%). On the basis of her research, Ammerman challenges the assumption that religious liberalism is a spent force, and that liberal religiosity is a paler reflection of conservative Christianity. The Golden Rule Christianity she describes is characterized by an emphasis on the primacy of good deeds motivated by love, care, and compassion, and by a belief in the importance of religious tolerance.

Liberal Christians remain in positions of dominance throughout the West. The sectarian Protestantism amplified by Kelley (1972) and others had no influence on the character of Christianity in Europe, though it has profoundly affected African Christianity. The antimodernist impulse of sectarian groups hinders their members' ability to succeed in broader society, and liberal Christians continue to dominate educationally, in politics, and in income and wealth attainment (Keister and Sherkat, 2014). Indeed, even in the few examples of sectarian Protestants attaining positions of power, most, like US Presidents Jimmy Carter and Bill Clinton, are liberal Christians. Growing ethnic diversity also bodes well for liberal Christianity, since social justice orientations fostered by liberal Christianity are attractive to ethnic Christian minorities, particularly in the United States. Perhaps most importantly, the liberal Christianity has embraced individual liberty on issues of sexuality and gay and lesbian rights, in contrast to sectarian Christianity, and the increasing embrace of sexual freedom and civil rights for gays and lesbians makes these groups more attractive to younger generations (Sherkat, 2014).

Sociological Interpretations

At least three clusters of explanations have been offered by sociologists of religion to account for the rise of liberal Christianity in modern times. It has been explained as (1) an accommodation or even a capitulation to modernity (Peter Berger), (2) a natural outgrowth of Protestantism and, in particular, of the liberal Protestantism's emphasis on personal subjective conviction (Ernst Troeltsch), and (3) a means by which the clergy, their social status undermined by modernity, have attempted to protest and regain a social role (Jeffrey Hadden). Woodhead and Heelas (2000) have also drawn attention to liberal Christianity's compatibility with modern socioeconomic formations and wider cultural trends such as the turn to the self.

Sociologists have also developed theories to account for liberal Christianity's apparent decline. Kelley explained this by drawing a contrast with conservative religion. Where the conservative Christianity was 'strict' and 'challenging,' the liberal Christianity was the opposite. As such, he argued, it was unable to generate or sustain commitment, consensus, or strong community. Peter Berger offered a more rigorous version of this explanation by arguing that plausibility is a function of unanimity. The strong, unified communities that characterize conservative religion are better able to sustain plausibility than are the more diffuse and less disciplined communities of liberalism. Meanwhile, sociologists like Talcott Parsons and David Martin have also argued that liberalism is a victim of its own success: because its beliefs and values are so close to those of the wider culture, it is no longer able to sustain a distinctive identity or to hold or attract adherents.

Much of this theoretical work depends on a contrast drawn between liberal and conservative Christianity. It is also important to note another boundary: that between liberal Christianity and radical or 'alternative' forms of spirituality. For while the fate of liberal Christianity is bound up with that of conservative Christianity, it is also bound up with that of new forms of religiosity like the New Age. In some ways the latter seems to represent an intensification of key liberal themes like individualism and freedom, but without liberal Christianity's continuing commitment to some form of institutional church. It remains to be seen whether the apparent growth of such religiosity will in the end have the effect of strengthening or of weakening liberalism.

Abstract

Over the past 15 years, anthropologists have increasingly turned their attention to liberalism. A contemporary anthropology of liberalism concentrates on how liberalism shapes anthropological knowledge practices and how liberal norms are lived and inhabited. Ethnographic work analyzes how liberal values are encountered, appropriated, rejected, and reworked by people who claim liberalism as an autochthonous tradition and by those who have been historically cast as liberalism's 'others.'

Over the past 15 years, anthropologists have increasingly turned their attention to liberalism, a set of political, philosophical, and economic doctrines, policies, and practices with roots in seventeenth- and eighteenth-century Enlightenment thought. In growing recognition that liberalism persists as "the most dominant ethic of our age" (Mahmood, 2007: p.148), which "polices the boundaries of the speakable and the unspeakable today" (Boyer and Yurchak, 2010: 180), anthropologists examine how various forms of liberalism frame social science epistemology as well as how liberal norms shape the conditions of possibility for human sociality globally. Recent ethnographic work analyzes how liberal values are encountered, appropriated, rejected, and reworked by people who claim liberalism as an autochthonous tradition and by those who have been historically cast as liberalism's 'others.' With the profusion of scholarly attention to the contours and impacts of neoliberalism, it has become ever more necessary to understand liberalism's history and wide ranging contemporary force.

Defining Liberalism

Given the pervasive hegemony of liberal norms, forging a cultural analysis of liberalism is no small task. Liberalism is deeply intertwined with projects of modernity, colonialism, capitalism, and democracy, making the work of parsing liberalism's unique characteristics or referents difficult if not impossible. To conceptualize liberalism in anthropological terms requires viewing the tradition of liberalism as 'heteroglossic' meaning that it is "under constant negotiation, reformation and critique through the very vicissitudes of everyday life" (Coleman and Golub, 2008: p.258; Goodale, 2008). Liberalism is best defined, then, as an ever-changing project rather than a specific historical period, narrow political philosophy, or type of society.

For many students, a discussion of liberalism is plagued by a basic confusion about what liberal or liberalism connotes. In the contemporary period 'liberal' sometimes indexes a progressive political position in support of a social welfare state and other state intervention. Yet, in many contexts, 'liberal' signifies a conservative advocate of free markets. Conflicting beliefs recognized as liberal values can, in fact, be traced to the same body of work of scholars and philosophers who have been categorized retrospectively as the founders of liberalism, such as John Locke and Adam Smith.

Liberal thought is generally predicated on a belief in the unilineal progress of humankind, made possible through the robust application of reason. Liberalism consists of manifold traditions, some dedicated to individual liberty, others more concerned with social equality. Liberal ideals were first formulated in western Europe in opposition to feudal society with the aim of redefining the limits of political authority. Proponents opposed the arbitrary power of the King and the privileges granted by birth to the nobility. The development of liberal thought involved the formulation of a new notion of the individual. The sovereign, according to early liberal thinkers, needed to be subordinate to the liberty and rights of the individual.

According to early and more recent proponents, liberal governments must be powerful enough to secure individual liberty but limited enough that it cannot impose restraints on individuals. The philosophical basis on the liberal state is a doctrine of natural rights that all 'men' possess fundamental rights (life, liberty, security, and happiness) on which the state must not tread. Whether individual autonomy is the aim of liberal governance that needs to be produced through state intervention or a naturally occurring condition of humanity has long been a key fault line within liberal doctrine (Hindess, 1993).

A rights-based state, according to liberal doctrine, is meant to employ constitutional mechanisms to guard against the misuse of power, respect due process, and guarantee equal protection against the tyranny of the majority. Liberal government proposes to manage a balance between order and liberty by identifying domains that are purportedly 'outside' politics, such as the market and civil society. The state is obligated not to limit the autonomy of these supposedly naturally existing autonomous spheres. Contemporary proponents such as John Rawls (1993) argue that political liberalism is uniquely able to foster pluralism by creating conditions that can tolerate conflicting moral, religious, or philosophical beliefs while avoiding comprehensive ideas or unitary visions about 'the good.'

Rather than formulate a comprehensive analysis of liberal political reason and its genealogy, anthropology has sought to document and analyze the everyday effects, lived contradictions, impasses, and potentialities of liberal approaches to the individual, law, the state, reason, difference, property, and freedom (among other concepts). Ethnographic analyses of how people encounter liberal concepts illustrate that liberalism is far from

neutral in regards to notions of the good, imposing particular norms, morals, and values (Comaroff and Comaroff, 2004; Gledhill, 1997) as well as a belief in a transcendental rational subject whose freedom is linked to an individual will to act autonomously (Mahmood, 2004, 2007). A contemporary anthropology of liberalism concentrates first and foremost on how liberalism shapes anthropological knowledge practices and how liberal norms are lived and inhabited.

Precursors

Recent anthropological explorations of everyday experiences of liberalism have been driven by two key developments. Foucault's scrutiny of liberalism as a rationality of rule greatly influenced the direction of much anthropological scholarship. Foucault approached liberalism not as an ideology or a philosophy but instead as a way to craft governance and practice freedom and discipline (Foucault, 2009; Rose, 1996). Rather than accepting at face value claims that liberalism seeks to defend freedom and distribute power, building on Foucault and poststructuralist scholars, anthropologists turned to examine how liberal thought organizes, constitutes, and defines power and freedom. Moreover, beginning in the 1990s, anthropologists began to devote extensive attention to the impacts of the post-Cold War narrative that liberal capitalist democracy had proven itself as the only viable form of human organization and to the application of this world view in the form of neoliberal policy and ideology. The growing influence of neoliberal thought has created a pressing need to understand this most recent variant of liberalism within a broader framework.

Anthropology's engagement with liberalism, however, begins much earlier, as anthropology is itself a product of liberal enlightenment thought. While this article focuses on the anthropology of liberalism – the self-conscious engagement by anthropologists of the meaning and uptake of liberal logics in peoples lives – one must also consider, to paraphrase Joan Vincent (1990), the liberalism of anthropology. Like all social science disciplines, anthropology is both a creation and critic of liberalism in its different historical iterations: from the Enlightenment, colonial and anticolonial projects, 'scientific' racism and antiracist scholarship, struggles over the development of the welfare state in the United States and Western Europe, the Cold War, the rise of neoliberal ideology, and the recent 'War on Terror.' Early anthropology built on and developed ideas and commitments of western European enlightenment thinkers, including 'community,' 'civil society,' 'contract,' 'secularism,' 'cosmopolitan' and principles of equality, universal humanity, individual rights, progress, private property, and reason (Vincent, 2009). Early and mid-twentieth-century anthropology embraced certain liberal precepts and contributed to the distinction and, hence, the formation of different civilizational orders and peoples according to liberal metanarratives of progress and modernization (Ferguson, 1999; Asad, 1973).

While anthropologists were complicit in the exclusion of non-Europeans, women, and workers from nineteenth- and twentieth-century liberal and colonialist claims for who was considered a reasonable and equal subject capable of self-rule, anthropological critique and knowledge has also long been mobilized to counter such exclusion. Anthropology has struggled over the internal tensions and multivalent possibilities of liberal ideals, observable in Franz Boas' antiracist cultural relativism and debates of the late 1940s over the Universal Declaration of Human Rights, when Melville Herskovits condemned the claim that European derived values were universally applicable. American anthropology advocated respect for pluralism and tolerance of different cultures. Anthropology's relativist stance fortified a homogenous and bounded notion of culture, which further strengthened the conceptual divide between the purportedly normative rational individual of the West, and liberalism's 'others,' the allegedly politically inadequate subject of the non-West. Contemporary scholarship on human rights, multiculturalism, and cosmopolitanism reviewed below, continues to debate the questions of liberal relativism and universalism first raised by mid-twentieth-century anthropology.

Marxist and feminist anthropology, which gained traction and legitimacy in 1960s and 1970s, generally dismissed liberalism as a cover for capitalism. Influenced by Marx's skepticism for liberal or 'bourgeois' political economy, advocates of this turn questioned the concept of the atomized autonomous individual or culture group and called for more direct engagements of anthropologists in politics as well as acknowledgment of global interconnection within relationships of unequal power (Wolf, 1982).

More recently, anthropologists have rejected the Cold War's projection of liberalism and socialism as diametrically opposed, building on scholars who understand these movements as deeply intertwined utopian projects, both of which grow out of the Enlightenment, and have long been defined in relationship to each other (Buck-Morss, 2000). Concepts or analytics that developed under late socialism, such as forms of political parody, prove to be useful tools to denaturalize the logics of recent manifestations of liberalism or, what anthropologists have recently begin to call 'late' liberal politics (Boyer and Yurchak, 2010).

Liberalism's Diaspora, Moral–Ethical Aspirations, and Global Force

Contemporary anthropological scholarship explores how liberal ideas become embedded in disparate contexts and have been a resource for marginalized peoples to critique Western domination in the colonial and postcolonial period. Liberalism has been and continues to be a product of the confluence between the colonizer and the colonized. Under the duress of anticolonial struggles and social movement claims for inclusion and democratization, liberal ideals have shifted over time (Goodale, 2008; Mahmood, 2004; Povinelli, 2006). Anthropologists document the tension inherent in systems of liberal democracy that allows for the disempowered or oppressed to draw on liberal principles of equality and liberty in order to make claims on a system that has excluded them often on the basis of these same principles. Mark Goodale argues, for example, that rather than 'conscripts' of liberal modernity, as David Scott might argue (2004), marginalized peoples are 'alchemists' (2008: p. 170).

Yet, even as liberalism's ideals are pressured to embrace an expanding view of who 'counts,' liberal normative assumptions continue to exclude certain "projects and moral–ethical aspirations" (Mahmood, 2007: p. 149). Anthropologists uncover the moral sensibility that remains hidden in liberal commitments to universal recognition and rationality. Particular moral injunctions often deemed pretheoretical are embedded in liberal legal structures, making them far more imperceptible than in socialist contexts, where the connection between politics and moral positions have been explicitly cultivated and expressed by state actors (Roudakova, 2009). Povinelli (2002: p. 9) points out that liberalism is at an impasse when critical rational knowledge that is supposed to form the basis for reasonable decision making under liberalism does not align with a liberal moral sensibility.

A central concern for many anthropologists exploring liberalism's contemporary force is how, in the name of humanitarianism, liberal values are used to justify intervention in sovereign states that have been judged as forfeiting their right to self-determination because they have violated individual rights. The division between normative liberal subjects and inadequate or culturally repugnant 'others' continues to support projects of governmental and neoimperial intervention, most recently observable in the US-led 'War on Terror' (Abu-Lughod, 2002). This divide takes place using liberalism's key concepts as a measure of a 'Eurocentric index of accomplishment' (Comaroff and Comaroff, 1999: p. 17). Recent anthropological scholarship on liberalism, which I review below, focuses on exploring how ideas of individualism, freedom, human rights, state, civil society, freedom of expression, and multiculturalism are mobilized and experienced, and what they accomplish.

The Individual, Agency, and Freedom

A notion of the individual as a self-authorizing subject and the primary social unit is central to liberal thought. Liberal ideals of freedom and agency center on the individual. Anthropologists subject this concept of the individual to immanent critique, asserting that the autonomous individual subject is a normative historical construct and cultural artifact.

For decades, ethnographic work has focused on the development or local meanings of personhood. Marilyn Strathern's work in Melanesia, for example, refuted the universal applicability of the idea of the individual finding that Melanesians construed themselves not as authors of their internal selves, but as multiply constituted (1988: p. 119). More recent work has turned from refuting the universalism of the liberal category of the individual to examining how liberal subjectivity – a sense of individual self-authorship – is constituted in everyday life. In Lila Abu-Lughod's ethnography of television viewing in Egypt, she illustrates how state-produced televised melodramas encourage the constitution of the modern liberal subject, one that views the self as autonomous and self-activating (Abu-Lughod, 2005).

Feminist anthropologists have long noted that proponents of liberalism posit the liberal subject as universal, neutral, and abstract when, in fact, the individual autonomous individual is presumed historically to be a male head of household responsible for dependent women and children. Recent appraisals of feminist anthropology take previous scholarship to task, however, for reproducing liberal assumptions about individual agency. Saba Mahmood finds that poststructuralist feminist scholarship produced by anthropologists and others continues to insist that human beings have an innate individual will for freedom that is expressed when people assert their agency by challenging social norms (Mahmood, 2004: p. 5). In Mahmood's work on the women's piety movement in Egypt, she argues instead that "agentival capacity is entailed not only in those acts that resist norms but also in the multiple ways in which one inhabit norms" (Mahmood, 2004: p. 15).

Building on and reappraising poststructuralist critiques, a growing body of ethnographic work alongside Mahmood's challenges a liberal definition of freedom as being opposed to or liberated from norms or power. Anthropologists reveal how a liberal concept of freedom is mobilized as "a means of governance" (Englund, 2006: p. 9) and as part of a strategy to rule through the "regulated and accountable choices of autonomous agents" rather than through social institutions or the state (Rose, 1996: 160). Anthropologists provide empirical evidence of how liberal governance produces purportedly 'free' individuals through institutions such as schools, media outlets, human rights organizations, development initiatives, courts, and other sites to create self-regulating subjects. Liberal freedom, anthropologists and others argue, is particularly a mode of exercising power over ourselves and others (Rose, 1999).

Liberals lean heavily on the binary concepts of individual freedom and social constraint to differentiate civilizational orders and peoples, and to govern love, access to rights, sociality, and the body (Povinelli, 2006). Elizabeth Povinelli, a prolific anthropologist of liberalism, asks:

> Why does it matter, and to whom, that certain communities and their economic, ritual, and social practices be apprehended as 'free' and others as 'constrained'? What work does this dichotomy do in defining the social and political exceptionality of liberal forms of constitutional democracies? How does this dichotomy allow democratic institutions to exercise disciplinary force as if they were advancing freedom and protecting the good? (2006: p. 99)

In Povinelli's analysis of disparate groups in the liberal settler societies of Australia and the United States she goes to great lengths to answer these questions. She reveals how indigenous Australians are deemed trapped by their 'genealogical inheritance' or traditions, while queer radical faeries in the United States are caught within the same liberal logic but face different conditions of recognition of their rights given their purported individual freedom, agency, and lack of tradition. Being understood as 'free' or 'constrained' shapes the possibility of gaining recognition and rights. In a different context, Amahl Bishara uncovers how Israeli state forces deprive Palestinian journalists of rights by regarding them as hopelessly constrained or biased by their customs and history and thus lacking the ability for rational deliberation (Bishara, 2013). The liberal binary of freedom and constraint, anthropologists reveal, is crucial to legitimizing the liberal state's selective distribution of rights and resources at local and national levels and shapes neoimperial politics on a global scale.

In ethnographic inquiries into the lived experience of liberal ideals of individual freedom in the United States, anthropologists have examined how computer hackers negotiate and critique

liberal commitments to individual autonomy and property (Coleman and Golub, 2008). Hackers and free and open software developers draw on liberal ideals of self-reliance and individual liberty even while free software seems to violate the logic and principles of private ownership and individual autonomy (Coleman and Golub, 2008; Kelty, 2008). Free and open software proponents connect individual autonomy to the use of property, but as Coleman and Golub point out, "the use and enjoyment is enabled through sharing," not individual property rights (2008: p. 268). They create a "rival liberal morality" and translate it into a legitimate legal register (Coleman, 2009: p. 448). This ethnographic work uncovers the processes through which traditional liberal ideals persist and are transformed.

Civil Society and the State

Over the past few decades, anthropologists have exposed the way that liberal conceptions of 'state' and 'civil society' have become part of common sense ways of viewing political practice and space, both in mainstream accounts and in much social science literature (Ferguson, 2006). These concepts have multiple histories. The concept of civil society can be traced, for example, to eighteenth-century Scottish Enlightenment thinkers, and was subsequently reworked by a series of scholars from Hegel to Marx to Gramsci. The more recent appropriation and popularity of 'civil society' in the 1980s and 1990s was due to a confluence of forces: shifting world politics at the end of the Cold War, the conjunction of progressive grassroots organizing and neoliberal efforts, and the political economy of translation and academic publishing.

In most variants of liberalism, state and society are ideally separate and autonomous spheres. The state is seen as a set of external constraints on individual freedom, necessary for an ordered social existence but a threat to liberty. In order to study ethnographically how the state is understood and represented, anthropologists examine banal contact with bureaucracies and state institutions, the science and art of governance, and fantasies about the state. Akhil Gupta's groundbreaking ethnography (1995) uncovered how the boundaries between state and society are, in fact, blurred in everyday practice. Rather than a monolith set apart from everyday interactions and situated social relations, the state is an ensemble of local practices that include what are often considered civil society institutions. Commonplace bureaucratic practices as well as spectacular displays of power help produce an understanding of states as spatially above society and encompassing the local (Ferguson and Gupta, 2002; Coronil, 1997). Ethnographers assert that the supposed separation between state and civil society, so central to liberal thought, is produced by the way that governance is enacted and represented. The anthropology of liberalism thus challenges the actual existence of autonomous spheres of civil society and the state.

Liberal Law, Human Rights, Universalism, and Vernacularization

Human rights law (a branch of liberal law) and the possibility of its local vernacularization has been an enduring preoccupation of anthropologists since the 1940s. Ethnographic attention to human rights practices, organizations, and discourse illustrates how human rights discourse works as a "liberal vanguard of the contemporary imaginary" (Goodale, 2008: p. 127). Anthropologists have observed that politicians, scholars, and activists increasingly turned to a language of human rights to replace the grand narrative of liberal democratic freedom versus communist tyranny, which animated the Cold War in the west.

Anthropologists have 'provincialized' human rights discourse, highlighting its roots in European philosophy that promotes a particular individualized framework for social justice dependent on liberal notions of autonomy, equality, choice, and secularism (Merry, 2006; Wilson, 1997). Human rights discourse demands a sense of selfhood autonomous from family, religion, and community. This self is imagined to be protected by the liberal state, the central arbiter of justice, rather than community or kin. The ensemble of international nongovernmental and governmental agencies and organizations dedicated to advocating for universal human rights often seek to transform subjectivities to conform with modern liberal notions of the individual rational subject in ways reminiscent of colonial states.

Anthropology explores the ongoing internal contradiction within liberalism that simultaneously facilitates universalist and relativist claims for human rights, both of which can put to progressive or conservative ends and rely on essentialist notions of humanity or culture. As Tejani notes, "Relativism may respect essential difference, but first it must enumerate the essence of difference. Likewise, universalism may argue toward the essential commonality of human subjects, but first it must locate the essence of that commonality. In either case, it is clear, essentialism is a necessary tool for the relativist and universalist renderings of cultural reality" (Tejani, 2004: p. 335). Cultural relativism, as Abu-Lughod notes (2002), is an improvement on ethnocentrism and racism, but often overlooks the fact that the forms of life we see around the world are not pristine examples of essential human ways of being but rather the products of a history of intervention and interaction. A critical cultural relativism acknowledges power differentials within and across groups and that it may be 'too late not to interfere' in a given context when we acknowledge a history of intervention (Abu-Lughod, 2002: p. 786).

While anthropologists reject the universal liberal subjectivity and normative morality at the heart of human rights discourse, many continue to advocate for the rights and needs of marginalized populations. Yet the conceptual ground on which to fight for rights and resources is tricky terrain. While human rights discourse can be used to impose an untenable universalism or can reify essentialisms, many anthropologists search for a recognition of commonalities cross-culturally that can be used as a basis to fight for social justice unwedded from liberalism's secular humanism and essentialisms. Some scholars have begun to forge a framework of 'critical cosmopolitanism' as a normative basis of shared human commensurability not dependent on liberal norms or metanarratives (Werbner, 2008; Glick Schiller et al., 2011).

Acknowledging the far-reaching spread of human rights discourse across the globe, anthropologists have turned their attention to analyzing human rights discourse in action. Liberal human rights ideals are incorporated into domestic law, people

are encouraged to complain about problems in human rights terms, judiciaries are educated about international treaties and standards, and governments are monitored and pressured to be accountable. Rather than assume that concepts such as 'women's rights' have a knowable essential meaning or actual ontology, anthropologists trace the uptake and movement of these ideas, exploring what they are used to accomplish (Abu-Lughod, 2010). Anthropologists ask, how are liberal logics of rights locally appropriated, rejected, or hybridized? What are the outcomes of efforts at vernacularization?

Anthropologists contend that the contemporary human rights system is far from a coherent or unified approach, but is rather a disparate collection of mechanisms, policies, and declarations appropriated by subaltern groups, not simply imposed on them (Lazarus-Black, 2006). Yet, given how liberalism is highly inscribed in the language of law, access to legal literacy proves fundamental to challenge and transform liberal regimes (Coleman, 2009; Comaroff and Comaroff, 2004). Skills for technological and legal understanding are often quite compatible, making well-educated highly literate people such as computer hackers and free software writers – who Kelty (2008: p. 19) calls "superalterns" – especially equipped to challenge existing approaches to liberal law.

Ethnographic inquiries into the possibility that people can vernacularize or hybridize human rights law underscores the actual limits of liberal claims to openness and tolerance. Human rights professionals, anthropologists find, often position tradition or religion as an impediment to the cultivation of reason and equality necessary to secure universal rights. Even when local human rights advocates attempt to frame human rights issues according to local histories, the framing process is often restricted by commitments to liberal notions of justice, individual rights, autonomy, choice, and equality. Anthropologists have documented, moreover, how in the face of criticism of what human rights practitioners understand as local practices, groups often resort to affirming an essentialist cultural nationalism or religious fundamentalism.

Anthropologists have also recently explored what happens when people seek to legitimize their vocation or social movement within a liberal imaginary of human rights discourse even while their practices and experiences are structured by different understandings of politics and justice (Hasty, 2005; Roudakova, 2009; Schiller, 2011). Goodale, for example, finds that when marginalized Bolivians turn to a liberal human rights discourse grounded in rights to private property and contract law they ultimately restrict their ability to advance communal notions of equality and access to resources (2008: p. 152). Jennifer Hasty uncovers how Ghanaian journalists turn to essentialized notions of cultural difference in order to explain why their practice falls short of Western ideals of autonomy.

Despite trepidations concerning the often negative outcomes of attempts at vernacularization of human rights discourse, many anthropologists remain committed to a global liberal legal framework for its potential to secure rights and reparations.

Liberal Multiculturalism

Building on anthropological insight about human rights discourse, universalism, and relativism, scholars have recently explored the rise of liberal multicularism. Anthropologists note that states have created official policies of cultural recognition as a way to contain anticolonial and new social movements' demands for social justice. Multicultural policies and ideologies seek to sidestep the problems that capitalism and (post)colonialisms raise for defining national identities (Povinelli, 2011; Comaroff and Comaroff, 2003; Povinelli, 2002). These policies aim to valorize and accept cultural differences and identities without destabilizing the framework of liberal justice, which does not address socioeconomic inequality. Anthropologists explore the limits of the liberal multicultural embrace of pluralism and tolerance in the face of radical alterity, while pointing to the ways that multicultural discourse can also reinforce concepts of essentialized cultural and religious difference.

Liberal multiculturalism, anthropologists argue, both creates and contains difference. Difference, which is seen as an essence rather than a product of social relations, is marked and granted legal protection only if it does not seriously counter liberal norms for what is morally acceptable and legally tenable. Recognition of indigenous customary law in Australia, as Povinelli notes, is punctuated with an invisible disclaimer "provided [they] … are not so repugnant" (2002: p. 12). Minority subjects are required to provide evidence of enough difference so that liberal governments can demonstrate their tolerance and respect of multiplicity, but without asserting values that actually shake liberal legal or moral foundations.

Liberal multiculturalism often works as a form of domination by encouraging minority subjects to assert an essential authentic self. Cultural 'others' must demonstrate or perform a certain degree of alterity to merit recognition or entitlements. Nevertheless, indigenous subjects find ways to creatively engage liberal discourses of multiculturalism to fulfill needs. Liberal multiculturalism's stifling of local complexities, in other words, is not the whole story. John and Jean Comaroff maintain that in the 'policultural' postcolony of South Africa "a 'living constitution,' tolerant of everyday ambiguity is being forged in the space of strategic engagement opened up by the alternative languages and cultures of legality" (Comaroff and Comaroff, 2003: p. 245). While the formal prescriptions of the liberal state restrict the acceptance of multiple epistemologies or authorities, in practice a vernacular praxis embraces the ambiguous and multiple grounds of morality and reason.

Challenges to liberal claims of tolerance take place not only in postcolonial nations, but in former colonial powers. France's attempts to ban religious symbols from public institutions, for example, present anthropologists rich terrain to explore the malleability of liberal pluralism. Tejani (2004) explores how migrants in the European Union attempt to 'repatriate' liberal ideals of tolerance in ways that challenge historic parameters for national identity and sovereignty.

Understanding the *Neo* of Neoliberalism, the *Late* of Late Liberalism

Neoliberalism in not simply a revival of classical liberal political economy that advocates for a small state and a free market, but

represents instead the imposition of values of privatization, market freedom, and atomized individual responsibility to *all* spheres of human life. As Kingfisher and Maskovsky note (2008), many anthropologists approach neoliberalism through a materialist lens that highlights new concentration of class power and capitalist reorganization since the 1970s (Harvey, 2005), some embrace a poststructuralist perspective that emphasizes particular forms of governance and subjectification (Rose, 1996), while others highlight the specificities and contingencies that neoliberal ideas allow for citizenship (Ong, 2006).

Given the fervent critical attention devoted to the rise of neoliberalism, its imposition and the backlash against it, anthropologists and others have begun to insist on the importance of situating neoliberalism with the *longue durée* of liberal ideals and practices. Grasping the philosophical and political underpinnings of neoliberal ideas is important to overcome overly conceptual and totalizing approaches that endow neoliberalism with an agency all its own (Kingfisher and Maskovsky, 2008). Situating neoliberalism allows scholars to draw on the history of debates about liberalism's internal inconsistencies, potentialities, and lived impacts in order to better evaluate neoliberalisms contours and identify with specificity how people reshape social worlds using neoliberal policies and ideas.

Neoliberalism is one aspect of what anthropologists have begun to term 'late liberalism,' but does not represent the totality of how liberal norms are asserted and inhabited in the contemporary period. Recent ethnographic research highlights the characteristics of late liberalism, which include the effects of anti- and postcolonial and new social movements on how difference is treated in liberal states (Povinelli, 2011: p.103), the substitution of class or party affiliation with essentialized identities that champion culture rather than politics (Comaroff, 2011), as well as the 'hypernormalization' of authoritative political discourse that leads to modes of irony and overidentification (Boyer and Yurchak, 2010). 'Late' liberalism is not meant to mark a time period, but to signal the recent changes to liberal forms of governance and contemporary conditions of capitalism.

The recent concerns of anthropology of liberalism reviewed above fruitfully intersect with new directions in related fields of geography, sociology, political science, and literature.

Abstract

Liberalism is a sociopolitical idea about political order. It aims at creating a civil society, but adjusts its concrete demands to the existing situation of society and the state. This readiness to adjust has made liberalism willing to compromise as well as open to development. For this reason, the history of liberalism as an idea and as political practice can be adequately understood only as a continuing struggle about interpretation, but as controversial as the definition of liberalism has always been, liberalism has always aimed to make responsible citizenship possible. This is true for all societies, even if the paths liberalism has taken have differed in Europe, the USA, and other parts of the world. Europe is where liberalism originated and formed its liberal ideas of political order. For this reason, the article will concentrate on European liberalism. It will stress four aspects: (1) liberalism as an idea of political order; (2) liberal ideas of social and economic order; (3) liberalism and the nation; (4) liberal organization and milieus.

Liberalism is a sociopolitical idea about political order that has contributed substantially, since the late eighteenth century, to the modern age. It aims at creating a civil society, but adjusts its concrete demands to the existing situation of society and the state. This readiness to adjust has made liberalism willing to compromise as well as open to development. The core principles of liberalism endure, but the details of what it understands as civil society have changed in the course of history and have always been debated among liberals. For this reason, the history of liberalism as an idea and as political practice can be adequately understood only as a continuing struggle about interpretation, but as controversial as the definition of liberalism has always been, liberalism has always aimed to make responsible citizenship possible. This is true for all societies, even if the paths liberalism has taken have differed in Europe, the USA, and other parts of the world. Europe is where liberalism originated and formed its liberal ideas of political order. For this reason, we will concentrate on European liberalism.

Since its beginnings, liberalism has demanded three kinds of citizenship rights: (1) equality before the law, guaranteed by the rule of law; (2) equal opportunities for political participation, made possible by the right to vote and to participate in public life, and (3) the provision of the basic prerequisites for opportunities in life. The demand for equality before the law was made and fulfilled earliest. Then came political equality, though in practice liberals, in contrast to democrats, long favored giving different weights to the votes of members of different classes. Whether and to what extent the state should guarantee social rights has remained controversial among liberals to this day.

Liberalism as an Idea of Political Order

Liberal thinking centers on the individual, whose freedom of decision is to be defended against state and social constraints. All demands for individual freedom can thus be considered part of the liberal tradition. This would make liberalism as old as human memory, but a liberal doctrine of the state and society first arose in seventeenth century England. Its most influential thinker was John Locke (*Two Treatises of Government*, 1690). The European Enlightenment's attempts to limit Absolutism and to enable 'man's exit from self caused lack of self-responsibility' (Immanuel Kant) and finally the impetus of the American and French Revolutions (human rights, popular sovereignty, constitutionality) are further important stages of liberal thinking.

As political terms, 'liberalism' and 'liberal' were coined in Spain and did not establish themselves until after 1800. The nineteenth century was then the century of liberalism. No other sociopolitical idea of political order changed the state and society as radically. With the idea of the citizen, liberalism sketched a program for the future that was egalitarian in principle and that was directed against everything that limited individual freedom. At that time, this revolutionary program, which liberals nevertheless wanted to realize evolutionarily in step-by-step reforms, was directed primarily against absolutism and the rule of the nobility, and thus also against class and denominational privileges.

The liberals' central political demand was for a constitutional state. It was to guarantee the continuity of law, secure individual property, and enable the citizen to participate in the state. The liberals saw the absolutist state as their antagonist and wanted to tame it with constitutional law. The individual was to have free access to the public political arena and, as voters, exert influence on the state's decision making process, but the state was not to be stripped of its executive powers, only its functionings to be liberalized. The liberals did not call for a weak 'night watchman' state, but for freedom in and through the state. Liberalism's specific political program varied substantially from country to country and over time. What critics condemned as programmatic weakness or even as a betrayal of principles was precisely the strength of the liberal movement. Thanks to its flexibility, it was able to adjust its idea of political order to very disparate conditions of action. Liberals argued everywhere for the parliamentary form of government, but they also accepted compromises to avoid endangering the stability of state and social order.

Among the large European countries, the liberals' will to establish the parliamentarian system of government was

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62089-5

weakest in autocratic Russia and in preWorld War I, Germany. Liberals did not insist upon a particular form of state, but their ideal was parliamentary monarchy; they wanted to preserve the monarchy as a reserve constitution for states of emergency. This sharply distinguished them from the democrats, whose ideal was the republic. The European liberals of the nineteenth century were willing to accept the republican form of state (first in France and Italy), but, since the French Revolution of 1789, most liberals saw the republic as burdened with the odium of social revolution and the annihilation of civil society. The liberals' fear of social revolution put them at a distance from the idea of the republic, which could prevail only through revolution wherever monarchical states existed. In republican North America, this was not an issue. Limiting the power of the state and securing private property were the foci of American property-oriented, individualistic liberalism, which emphasized self-help and self-organization. Franklin D. Roosevelt's New Deal liberalism created the USA's first instruments for state intervention in society and economic policy.

In practice, the liberal idea of political order focusing on a society with egalitarian citizenship was compatible with inequality. The liberals of the nineteenth century wanted immediate implementation only of equality before the law; political equality could wait. They saw freedom of opinion and the right to vote as the most important means of apportioning participatory rights in the state and the community. By the early twentieth century, liberals had accepted democratic equal voting rights, but they never advocated or demanded the establishment of such rights. Rather, the majority of liberals accepted them only when they could no longer be avoided. The core of their idea of civil society was the economically self-sufficient, educated individual.

Liberalism offered an educational program for those who had not yet achieved this social status; the individual himself was to be responsible for its future fulfillment. This program was directed against a society that apportioned different political rights in accordance with membership in specific groups; but in the century of liberalism, the struggle against the historical and traditional society of privileges did not yet aim at the 'mass democracy' of the twentieth century. When the latter appeared on the horizon in the second half of the nineteenth century, liberalism had to change fundamentally if it was to survive party-political competition for votes. European liberalism was by and large able to cope with this adaptation until the beginning of World War I.

Emancipation to become a citizen with full rights not only developed at different paces for different classes, but also for the two sexes. Only a few nineteenth-century liberals could imagine woman as a citizen; one of these was John Stuart Mill (1859) *On Liberty and Other Essays*, an exceptional liberal figure precisely in the radicality of his emancipatory demand for gender parity. Not until the twentieth century did the majority of average liberals come to accept and recognize woman as having equal political rights. Until then, they used the idea of a naturally given eternal inequality of the sexes to avoid the consequences of their egalitarian model of law. Their constitutional idea of civil society was egalitarian, because it was based on the principle of contractual freedom for all. But they did not want to see this principle applied to the family.

Their refusal to politically equate man and woman turned out to have great consequences for their model of society, because they saw the family as the foundation of the state and civil society. In the long run, the liberals could not suppress the contradiction between their political model of an egalitarian civil society and their attempt to construe the family as fundamentally gender-hierarchical. The egalitarian philosophy of liberalism forged an intellectual weapon against the practice of liberal politics, which tolerated or even affirmed certain forms of political inequality. The golden age of liberalism ended with World War I, although its chances for development seemed more favorable than ever before. After all, the war ended in a victory for the Western democracies (USA, Great Britain, and France), which were regarded as the primary representatives of liberalism, while the monarchies of Central Europe and Russia did not survive the war.

Political liberalism did not sweep the field after the fall of these anti-liberal bulwarks. Instead, the signature of the new epoch was rivalry and finally struggle among the liberal-democratic and the new Bolshevist and fascist ideologies, movements, and states. The National Socialist dictatorship, in whose parlance 'liberalistic' was perverted into a life-endangering, denunciatory pejorative, finally threatened to extinguish forever the central idea of liberalism, the dignity of the individual, first in Germany and then in Europe's conquered states. The disintegration of liberal parties, including in Great Britain, the mother country of liberalism, continued after World War I and even after World War II, but at the same time, the constitutional orders and individual behavioral norms in the Western world have been characterized by fundamental liberal values more than ever before. Their validity is no longer tied to the strength of liberal parties. Liberalism's power to form parties appears to decline when its political ideas prevail and are recognized even by opposing political parties.

The collapse of the Soviet empire seems to confirm this observation. The successor states adopted liberal principles, or what they took to be liberal principles, in their new political and economic orders, but this triumph of liberalism over its communist antagonist has at the same time triggered a new international debate over the central principles of a liberal system of state and society (Ackermann, 1992). This debate focuses on the old problem of whether a liberal society can trust solely in the regulative miracle of the market or if it should strive to create a state that, through a 'combination of citizenship rights and chances for welfare' (p. 196), empowers all people 'to take part as citizens in the life of the society' and 'to enjoy the achievements of their time' (Dahrendorf, 1987, pp. 196, 219).

Ideas of Social and Economic Order

Historical liberalism arose in the pre-industrial age. It strove for a civil, rather than bourgeois society, in both its ideas of social and economic order as well as in its model of the state. With the idea of the citizen, European liberalism sketched a vision of the future of a society of citizens without great property-ownership differences that would have contradicted the liberal ideal of a middle-class society with a broad distribution of assets (Schapiro, 1958). This socially harmonious guiding idea was

directed against the class/feudal order, but did not initially field an industrial view of the world against it. Liberalism comprised a plurality of social ideas that, depending on a country's state of social development, ranged from agrarian models of the future (as in Hungary, Spain, and Italy) to industrial capitalistic models (as in the USA, Great Britain, Belgium, and, in part, France and Germany). The liberals demanded social and economic 'progress,' but not an industrial-capitalistic class society. Only after the mid-nineteenth century did pre-industrial liberal ideas of order pale in favor of industrial capitalistic ones.

This shift, pushed forward by the wave of revolutions of 1848, marked the transition from early liberalism to liberalism in the age of industrialization. Only now, when dynamic industrialization ended the pauperism of the first half of the century and sociopolitical control mechanisms seemed renouncable, did political liberalism fuse with *laissez-faire* economics. The main current of liberalism now became more bourgeois than ever before, without narrowing to a bourgeois economic liberalism, even in this phase of Manchester Liberalism. Even now, the liberals were not characterized by convinced affirmation of a free, unregulated market. The liberal demand for free trade among states did not rule out a willingness to accept and call for regulation of the market within the state.

Since the last third of the nineteenth century, the trend to eliminate social-welfare aspects of ideas of societal order in favor of *laissez-faire* liberalism was tempered by a renaissance of social-liberal guiding ideas. Like early liberalism, the New Liberalism, an international phenomenon, displayed a marked social responsibility, but it assumed the conditions of an industrial society in which the freedom of the individual would be ensured by a policy of social welfare. Liberals had originally contributed to the political climate that, since the 1880s, gave birth to social security laws, first in Germany and then in rapid succession in other countries. This launched a development that led to the modern type of social welfare state. In the United States, it was not until Roosevelt's New Deal that political theory allowed for the state's substantial involvement, in contrast to the traditional liberalism of interest groups (Lowi, 1979).

No less important was community liberalism, which played a key role in the building of infrastructure in the enormously expanding cities, a precondition of urban life. This community welfare policy ranged from improved hygiene through municipal provision of gas and electricity to the new parks, museums, theaters, and mass education facilities. The achievements of community liberalism show how intensely liberals participated in the communal protection of individual life chances when, in the face of social and economic developments, individual provisions were no longer adequate or possible for increasing segments of the population.

But the individual, not the collective, was still the focus of liberal norms and politics. The conviction that the individual must take priority over the collective distinguishes even the decidedly social liberalism of the late nineteenth and twentieth centuries from the other progressive movements, such as socialism. But the dwindling numbers of liberal voters since the early twentieth century, teaches us that the variant offered by the liberal parties as a mediation between collective welfare security and individual freedom to decide no longer had the persuasive power that had characterized the liberal guiding ideas of the nineteenth century.

Liberalism and the Nation

Beginning in the late eighteenth century, the demands for popular sovereignty and national self-determination became two sides of the same coin. Only states that were recognized as national states could prevail. Liberals took a leading role in making the nation the new supreme principle of legitimacy. Like liberalism, nationalism developed a model opposed to the existing order. Both demands aimed at a society ordered in accordance with egalitarian values, constituted as a state and employing a collective, and thus equally egalitarian concept of sovereignty. This was why nationalism historically arose as, and can still present itself as an ideology of liberation and a movement of emancipation, despite all nationalistic atrocities. Anyone who wanted to ally with nationalism had to accept this basic egalitarian stance. Liberals did so. In the nineteenth century, they became the spokesmen of national movements, formulated their goals, and provided their elites.

This symbiosis of liberalism and nationalism strengthened and shaped both. Liberalism's influence expanded far beyond its narrower primary bourgeois clientele, and nationalism developed a reform program promising more social as well as political democracy. The vision of a national civil society that expands citizenship rights into the social realm and promises to allow all to share in the resources produced by a society were visions of the future common to liberalism and nationalism. These promises of participation for all, regardless of social status, are what made these movements so unrivaled in attractiveness. Liberalism was one of the creators of this vision that, here too, uncoupled itself from liberalism. Socialists and conservatives both adopted it.

The task of mediating between the central liberal principle of the responsible individual and the collective claims of the nation was nowhere more urgent and difficult than in the multinational Habsburg monarchy (Judson, 1996). The attempt to de-escalate national conflicts through constitutional guarantees of the right to national cultural individuality failed, but it indicated a path that would be taken with the help of the League of Nations after World War I in Europe's new multinational nation-states. This second attempt failed as well, but fundamental principles based in the guiding liberal idea were formulated: the will of the individual must be central, and no collective has the right to disregard this individual will. Making cultural assimilation the precondition for national minorities to enjoy equal citizenship rights in a society with a different national majority contradicts the central convictions of historical liberalism as it had developed since the late eighteenth century, but liberals have often violated this principle in political practice.

Organization and Milieus

Even before the emergence of lastingly organized modern parties, liberals tried to penetrate the public sphere with their

ideas and to influence state politics. Liberalism had the most favorable conditions for influence where parliamentary institutions already existed.

Secret organizations with revolutionary intentions, on the other hand, were not part of the liberal arsenal for action, because liberal politics did not aim for revolution, but rather for institutionalized, constitutionally regulated cooperation in state politics. Liberals sought to avoid revolutions or to transform them as rapidly as possible into parliamentarily legitimated reforms and thus to put them in a legal framework.

After parliaments became more significant and male voting rights expanded, political movements that sought a voice in state politics could no longer renounce party organizations. Beginning in the second half of the nineteenth century, the liberals, too, formed parties, though this was more difficult for them than for their competitors on the right and left. The guiding liberal idea of the responsible individual, who would determine the 'common good' in free discussion, continuously acted as a certain obstacle to hierarchically organized decision-making procedures. Among the liberals, the party apparatus generally had less importance than the parliamentary groups and local dignitaries.

The guiding image of civil society that has been associated with liberalism since its beginnings is also reflected in its social profile: its focus is on citizens, not the bourgeoisie. The social origins of liberal spokesmen displayed a broad spectrum, especially in the early phase. Nowhere was it limited to the bourgeoisie. Even in Great Britain, the pioneer of industrialization, from 1859 to 1874, only about 21% of the liberal delegates to the House of Commons were entrepreneurs. In Italy and Spain, liberalism found a bulwark among the nobility, and in Hungary the nobility dominated completely. In France, Germany, and Belgium, the bourgeoisie took a more prominent place in leading liberal circles. Everywhere here, liberal opinion-makers were highly respected men from respected families. They stood at a distance from tradition, but did not break with it. This membership in 'good society' was an important precondition for the power of liberal ideas to prevail even in those states that denied liberals access to state offices. A strictly bourgeois liberalism could not have achieved this.

Since the second half of the nineteenth century, the social 'catchment field' of liberal parties narrowed. They became more bourgeois. Two lines of conflict increasingly limited the liberal milieu:

1. One of the liberal parties' heaviest losses was that the workers, whose number greatly increased during the process of industrialization, turned away from them. This happened earliest in Germany (beginning in the 1860s), while in Great Britain the first workers' party still worked together with the liberals in elections (Lib–Lab coalition), but the British liberals, too, lost their worker votes when the Labor Party rapidly grew after World War I.
2. The secularity of the state was always a central liberal credo. In political practice, this goal could be tied to religious tolerance, but also to a struggle against Church competencies and claims. Intense conflicts between the state and the Church broke out in many countries on the European continent in the second half of the nineteenth century. This greatly limited the extent of liberal milieus. Catholics loyal to the Church generally turned away from liberal parties, which they saw as representatives of laicism, but the situation was different in Great Britain. Until World War I, the Irish question tied Catholic voters to the liberals, whose strongest support came from nonconformist congregations.

Abstract

A doctrine with roots in eighteenth century thought, liberalism emerged in the nineteenth century as the prevailing ideology of Western capitalist societies and democracies. Philosophically, liberalism consists of a commitment to the ideals of equality, liberty, individuality, and rationality. However, liberals have divided over their social and political implications. Some liberals have believed these values to be inscribed within the very fabric of modern societies, reflecting the innovative technologies, social differentiation and free movement of labor, goods, and capital characteristic of the commercial and industrial age and its aftermath. Others have thought the links between the two are fortuitous and contingent, and that these and other related social changes, such as the growth of bureaucracy, potentially threaten liberalism. Politically united against traditional and hierarchical societies, liberals have differed, therefore, over whether liberalism requires various kinds of political support, such as the state regulation of markets, or merely the absence of any interference by either the state or others to the spontaneous and autonomous social activities of individuals. Meanwhile, critics of liberalism have either blamed it for all contemporary social ills or regarded it as a transitory phase to be replaced by superior forms of social organization.

A doctrine with roots in eighteenth century thought, liberalism emerged in the nineteenth century as the prevailing ideology of Western capitalist societies and democracies. Though much transformed by the social and political developments of the twentieth century and seriously challenged by the various movements associated with them, especially fascism and socialism in the first half of the century and feminism, ecologism, and multiculturalism in the second, liberalism has retained its dominant place. It combines philosophical, social, and political elements. Philosophically, liberalism consists of a commitment to the ideals of equality, liberty, individuality, and rationality. However, liberals have combined these concepts in numerous and often opposed configurations, which reflect different social assumptions. Many liberals have believed these values to be inscribed within the very fabric of modern societies, reflecting the innovative technologies, social differentiation, and free movement of labor, goods, and capital characteristic of the commercial and industrial age and its aftermath. Others have thought the links between the two are fortuitous and contingent, and that these and other related social changes, such as the growth of bureaucracy, potentially threaten liberalism. Politically united against traditional and hierarchical societies, liberals have differed, therefore, over whether liberalism requires various kinds of political support, such as the state regulation of markets, or merely the absence of any interference by either the state or others to the spontaneous and autonomous social activities of individuals. Meanwhile, critics of liberalism have either blamed it for all contemporary social ills, or regarded it as a transitory phase to be replaced by superior forms of social organization. Liberalism has featured in social science in correspondingly divergent ways: as the 'natural' value system of modern societies, as a historically and culturally specific phase of social development, as either pernicious or expressive of basic human goods.

Liberalism Defined

For analytical purposes it is convenient to break liberalism down into its philosophical, social, and political components, though these form a package that different liberals have interpreted in diverse ways.

Liberal Philosophy

At a philosophical level, liberals seek the maximal equal liberty possible for all individuals to rationally and freely choose and realize their various projects and preferences without interfering with each other. This position draws together the concepts of equality, liberty, individuality, and rationality in a distinctive way. Liberals value equality in the sense of denying that anyone is the natural subordinate of others. This view does not entail regarding people as the same, merely that everyone has equal moral worth. Instead of seeking equality of outcome like certain socialists, liberals simply desire that all should have an equal opportunity to deploy what talents they do possess on the same basis as everyone else. Their attachment to liberty follows from this interpretation of equality and its implicit endorsement of the moral primacy of the individual. Among moral equals, individuals should be allowed to pursue their own good in their own way to the extent that is compatible with a like liberty for others. Finally, as rationalists, liberals believe that individuals should behave in a coherent and consistent manner and that decisions in the public domain should be open to critical scrutiny and amendment and capable of attaining the reasoned assent of those they affect.

Though liberals share a moral ethos and broadly agree on the conceptual relationships between liberalism's core values, they offer very different interpretations of them reflecting a wide variety of epistemological and ontological perspectives. Thus, liberals include methodological individualists such as Adam Smith or Herbert Spencer and holists such as Emile Durkheim, materialists such as John Locke and idealists such as T.H. Green or Benedetto Croce, utilitarians such as J.S. Mill and natural rights theorists such as Tom Paine, abstract universalists such as Kant, and historicist relativists such as Herder, and so on. Moreover, their main practical differences stem less from these considerations than from contrasting social visions and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03204-9

political judgements. Though individual thinkers naturally relate these last to their particular metaphysical and methodological views, the connections between them are far from clear cut. Similar theoretical perspectives often generate quite different practical stances, while thinkers of quite diverse theoretical positions may often be in substantial practical agreement.

Liberal Society

Historically, the most significant social influence on the formation of liberalism was the passage from feudalism to capitalism from the sixteenth to the nineteenth century. This fueled the liberal attack on ascribed status and its commitment to equality of opportunity. The closed feudal order of inherited rights, with its hierarchical system of aristocratic privileges, was to give way to an open and egalitarian capitalist order, in which an individual's social position and success supposedly mirrored his or her ability and effort – a way of life they felt was best realized in a free market economy.

Some contemporary liberals and many of liberalism's critics regard the ethos resulting from such social origins as essentially materialist, instrumental, and egoistic. Traditionally, however, liberals have been extremely wary of such attitudes and have sought to avoid them. The liberal conception of economic behavior emerged from the experience of the entrepreneurs, traders, shopkeepers, and artisans of early capitalism, and invokes the image of an idealized market order in which rewards are closely linked to effort. This linkage was codified in the labor theory of value and, in the British and North American context at least, drew additional support from the religious beliefs of certain Protestant sects that encouraged industriousness as a mark of salvation. The market also acts as a discovery mechanism, with competition and the profit motive weeding out bad practices and poor products whilst stimulating the search for new processes and commodities, and so promoting the progress of society.

Liberals have disagreed, however, over how far a policy of *laissez-faire* can secure these advantages, and doubts have grown as capitalism has taken on a more corporate form. Most have accepted the need for some regulation to protect the market against itself and maintain its freedom – such as anti-trust and monopolies legislation. Others have sought to distinguish between the economic and social disadvantages that individuals are responsible for and those they are not, supporting quite extensive unemployment insurance and state-supported training schemes, for example, to get the unintentionally out of work back into jobs. Finally, liberals have always acknowledged certain public goods will be badly provided or even neglected by market mechanisms, even if some have believed state provision could employ market elements such as competitive tendering – defense and certain infrastructural goods, such as light-houses, were the classic cases. Clean air, education, and a health service serve as more recent and contentious examples.

Liberal Politics

The political face of liberalism follows on from the philosophical and social elements outlined above but was additionally influenced by the wars of religion and the rise of modern science in the sixteenth and seventeenth centuries, which fueled calls for religious toleration and the related belief in rationalism and the moral equality of individuals. Along with the shift from social structures based on status to contractual relations between civic equals, these commitments led to the demand that politics reflect liberal principles. The state, like society as a whole, came to be seen as a voluntary association held together by the mutual consent of its members rather than the ties of deference to social superiors – a conception of political order summed up in the theory of the Social Contract.

The basic components of a liberal political system were established in the wake of the British, American, and French revolutions of 1688, 1776, and 1789, respectively. All three gave rise to new constitutional settlements and bills of rights. Two criteria informed these arrangements. First, laws were to be framed and applied impartially and universally. There were to be no special exemptions for particular groups, such as clerics and nobles, as in the past. Second, the laws were to guarantee to the greatest extent possible the equal right of each individual to pursue their own plan of life. For the majority of liberals, the most basic rights in this respect were traditionally the rights to private property and freedom of belief. These rights were essential to their understanding of the virtues of the market mechanism and of toleration, which they regarded as the embodiments of the new ethos.

At the heart of liberal politics is a distinction between the state and civil society (*see* State and Society: History of the Concept). The purpose of the state is to facilitate social interaction rather than to substitute for individual initiative through state control of social institutions. The latter is the mark of dictatorships in liberal eyes. However, social liberals nevertheless believe economic intervention and state provision of certain social goods can have an enabling role, though market liberals contend such steps undermine liberalism. Liberals are also often said to favor a related distinction between the public and private sphere, allowing behavior in the latter they would ban or restrict in the former. However, this distinction has never come out cleanly. To the extent liberals do distinguish between the two it is as a corollary of their views of the state's role in regulating society. The marriage contract, for example, offers a quintessential liberal device of a public character with a clear impact on private behavior. Just as liberals of different hues dispute the degree to which workers are free to sell their labor and the extent to which a valid contract implies certain standards of pay and conditions, so they have also debated whether and in what ways the marriage contract constrains the behavior of couples and grants women, in particular, rights to common property and protection against rape and abuse.

We have already disputed the view of liberalism as promoting possessive individualism in the socioeconomic sphere. A related objection contends that liberals advocate subjectivism, skepticism, and relativism in the political sphere, with all views treated as little more than personal opinions. However, the liberal insistence on the individual's right to follow his or her own path does not entail regarding all ways of life as equally valuable. Drawing on the experimental method in modern science and the Protestant defense of freedom of conscience, liberals contend that truth and morality emerge

through individuals being allowed to call into question accepted doctrines and try out new and occasionally eccentric or potentially offensive pursuits. Ideas have to be tested for their validity while personal virtue only comes from our taking responsibility for our lives. For the state or any group to paternalistically impose its views on the rest of society risks falling into dogmatic error, demoralizes the population, and produces stagnation. Individuals must be able to make mistakes so that they can learn from them and emerge morally and materially improved.

Nevertheless, liberals have seen no need to tolerate the 'intolerable,' defined as views that are incompatible with treating others as moral equals. Some critics have regarded this position as inconsistent with liberalism's claims to openness. Yet certain limits are clearly implicit in liberalism and would otherwise render it incoherent. Where exactly these boundaries lie and their legitimacy and justifiability are more contentious matters, however. Liberalism has been accused of a gendered, imperialist, and Euro-centric bias, and historically this has often been the case, albeit to differing degrees and with certain important if qualified exceptions, such as J.S. Mill's attack on the *Subjection of Women*. How far gender and multiculturalism remain a blind spot is less clear. Many contemporary liberals maintain that multicultural, gay, and feminist demands for recognition and respect, like other appeals against unjust discrimination, implicitly invoke liberal norms of equality and tolerance. They have simply revealed these principles to have a broader application than certain past liberals had appreciated.

The complexities of the liberal position emerge when we consider their ambivalent view of democracy. Liberals have recognized that democracy offers a means for holding governments to account, obliging policies to be justified and improved through critical debate, and allowing politicians to be peacefully removed when they prove incompetent, biased, or corrupt. However, past liberals sought to limit political citizenship to those with the intellectual attainment and economic resources they believed were required for 'independent' rational decision making – criteria that usually had the effect of ruling out workers and women. Even so, liberals worried about the 'tyranny of the majority' as represented by an irrational and dependent mass, whose votes could be bought by unscrupulous populists willing to pander to their prejudices and interests. As a result, liberals have tended to insist on the need for constitutional safeguards to protect liberal values from being overturned by democratic decisions.

Liberalism and Modern Society

Social scientists have seen liberalism as either an inherent and defining characteristic of modernity or as threatened by it. Amongst the first camp, moreover, there are those who see it as symptomatic of modernity's ills rather than its advantages, identifying liberalism with a possessive individualism that is not only antisocial but antisociological as well.

Liberalism as the Ethos of Modernity

The view of liberalism as the ethos of modernity was best expressed by British social scientists such as Adam Smith, Herbert Spencer, J.S. Mill, T.H. Green, and L.T. Hobhouse, and to a lesser extent French thinkers such as Benjamin Constant, Francois Guizot, and Emile Durkheim. For these thinkers, liberalism's philosophical commitment to expanding equal individual liberty was underwritten by a theory of social evolution whereby potential conflicts between different liberties would be harmonized. This latter thesis idealized the market relations between small-scale entrepreneurs characteristic of early capitalism. These were taken as a model of a meritocratic society of self-reliant and responsible citizens, who freely contract with each other for mutual advantage. Liberal politics was conceived as the superstructural products of these social and economic changes. Freedom, reason, morality, and progress came in this way to be identified, with an optimistic account of social development supporting an implicitly ethical naturalist philosophical belief in the compatibility of different forms of self-realization.

Adam Smith's doctrine of the 'invisible hand' of the market and Herbert Spencer's characterization of the 'industrial' form of organization as realizing the 'Law of Equal Freedom' offer classic examples of this position. The first a product of the commercial society of the eighteenth century, the second of the early industrial age of the 1840s, by the late nineteenth century the concentration of capital and the rise of organized labor had made liberals rather less sanguine about the inevitability of their vision. To the dismay of Spencer and other adherents of the earlier 'classical' liberalism, liberals began to envisage a more proactive role for the state in sustaining favorable social conditions. T.H. Green and L.T. Hobhouse, for instance, saw policies such as factory hours regulation and unemployment insurance as mechanisms for promoting freedom of contract and freeing individuals from certain structural constraints. Importantly, though, both saw the state as reducing the mutual interferences between individuals and fostering autonomy. In a similar manner, Durkheim argued that the liberal 'cult of the individual' was inherent to industrial societies and that the modern division of labor fostered an organic solidarity between autonomous agents. However, he had to confront various commercial crises, bankruptcies, and conflicts between capital and labor that suggested a less harmonious picture. He attributed these disturbances to contemporary societies being in a 'transitional phase' in which people had yet to fully assimilate liberal social norms. He too saw a role for the state in fostering these attitudes, with various 'intermediary institutions' serving to inform state policies as to social needs and act as a counter weight to state oppression of the individual (*see* Social Question: Impact on Social Thought).

Critics of liberalism sometimes portray this supposed relationship between liberalism and modernity in negative terms. They associate liberalism with a naturally instrumental and individualist model of human behavior, a disposition they believe is encouraged by the liberal conception of the market and democracy. They also claim it produces a view of social science as following the physical sciences by elaborating general laws of social development on the basis of various constant human passions. Some commentators have even argued that it was only radical and conservative opponents of liberalism who appreciated the distinctiveness of the human sciences by noting, respectively, how human behavior was modified by social structures and by culture, and the capacity of

individuals to interpret and evaluate circumstances in different ways. At best, liberalism results in a positivistic bourgeois ideology that ignores the impact on human thought and action of material conditions and productive forces, historically evolving communal traditions and conventions, and the possibility for reflective criticism. Thus liberalism is associated with certain behaviorist versions of political science and economics but not with sociology or anthropology. These arguments result from a highly selective and tendentious reading of the liberal tradition whereby, for example, De Tocqueville becomes a 'conservative,' Durkheim either a 'conservative' or a 'socialist,' and Herbert Spencer, read as an advocate of egoistic possessive individualism, becomes the exemplar of liberal social science. The liberal tradition, however, is much more diverse than this caricature, both methodologically and substantively. The vast majority of liberals distinguished respect for 'individuality' from 'egoism' and even positivist behaviorists, such as J.S. Mill, appreciated that autonomy only flourished given certain material conditions, cultural values, and economic structures and played a part in its turn in how these were fashioned in the future. This awareness of the social and historically contingent character of liberalism is no more evident than in those liberals who saw it as being undermined by modernity.

Liberalism as Threatened by Modernity

The threat posed to liberalism by elements of modernity was especially evident in countries such as Italy and Germany, where a modernizing economy and society went along with fragile and incomplete liberal regimes which ultimately succumbed to fascism. The challenge these developments posed for liberal social science is powerfully illustrated by the 'frustrated' liberalism of the Italian Vilfredo Pareto and the 'disenchanted' liberalism of Weber. Though commonly categorized as sociologists, their work ranges over the whole gamut of the social sciences, covering economics, politics, and, in Pareto's case, social psychology. Pareto was in many respects a sophisticated exponent of the instrumentally rational actor model of liberal individualism and was initially a strong advocate of both *laissez-faire* economics and a libertarian and democratic politics. However, he became convinced that what he called 'logico-experimental' thinking was the exception rather than the rule. Instead, most conduct was 'nonlogical' and arose from certain common psychological dispositions of either a conservative or more inventive kind. Politics simply consisted of the manipulation of these psychic states, a process that had been greatly aided by contemporary mass democracy. The electorate was too large and poorly informed and the decisions needed too numerous and diverse for rational debate to be possible. Democracy simply allowed populist leaders to legitimize their rule via emotive appeals to a popular will that was largely of their own making. He even briefly supported fascism as a possible way of breaking free from this system and establishing a liberal market order from above.

Weber, by contrast, offered a more historically and sociologically nuanced account of similar phenomena. He disputed that economic development per se fostered liberalism or that liberal values could be justified a priori. Liberalism's apparent basis in natural law had been historically contingent, reflecting the peculiar social and political experiences of early modern Europe outlined above. Not only was this constellation of factors unlikely to reappear, but even within established liberal regimes liberalism was threatened by the spread of economic instrumentalism, bureaucratic rationality, and corporate organization resulting from the further development of capitalism. The chances of liberal democracy being established in societies such as Russia, which had not benefited from the earlier favorable historical experiences, were minimal, therefore. Quite different cultural values were likely to shape the modernizing processes of such societies, as indeed has occurred throughout Asia where capitalism has by and large taken a nonliberal form. Meanwhile in already existing liberal societies, the autonomous action characteristic of liberalism was possible only for the political leaders and entrepreneurs who controlled and gave direction to the various political and economic administrative structures that govern our lives (*see* Modernity).

Most contemporary liberal thinkers regard Weber as too pessimistic and many believe liberal values can be justified on grounds distinct from their historical and social origins. However, the possible disjunction between late modernity and liberalism, on the one hand, and the search for liberal foundations that appeal to reasons that ought to be accessible to all and so compatible with a variety of different cultures and ideals, on the other, remain the prime challenges a viable liberal theory has to meet.

Abstract

A doctrine with roots in eighteenth-century thought, liberalism emerged in the nineteenth century as the prevailing ideology of Western capitalist societies and democracies. Philosophically, liberalism consists of a commitment to the ideals of equality, liberty, individuality, and rationality. However, liberals have divided over their social and political implications. Some liberals have believed these values to be inscribed within the very fabric of modern societies, reflecting the innovative technologies, social differentiation, and free movement of labor, goods, and capital characteristic of the commercial and industrial age and its aftermath. Others have thought the links between the two are fortuitous and contingent, and that these and other related social changes, such as the growth of bureaucracy, potentially threaten liberalism. Politically united against traditional and hierarchical societies, liberals have differed, therefore, over whether liberalism requires various kinds of political support, such as the state regulation of markets, or merely the absence of any interference by either the state or others to the spontaneous and autonomous social activities of individuals. Meanwhile, critics of liberalism have either blamed it for all contemporary social ills or regarded it as a transitory phase to be replaced by superior forms of social organization. However, contemporary liberals seem increasingly critics themselves of the inequality and abuse of rights found in modern societies, although how far their proposals can be made a reality remains uncertain.

A doctrine with roots in eighteenth-century thought, liberalism emerged in the nineteenth century as the prevailing ideology of Western capitalist societies and democracies. Though much transformed by the social and political developments of the twentieth century and seriously challenged by the various movements associated with them, especially fascism and socialism in the first half of the century and feminism, ecologism, and multiculturalism in the second half, liberalism has retained its dominant place. It combines philosophical, social, and political elements. Philosophically, liberalism consists of a commitment to the ideals of equality, liberty, individuality, and rationality. However, liberals have combined these concepts in numerous and often opposed configurations, which reflect different social assumptions. Many liberals have believed these values to be inscribed within the very fabric of modern societies, reflecting the innovative technologies, social differentiation, and free movement of labor, goods, and capital characteristic of the commercial and industrial age and its aftermath. Others have thought that the links between the two are fortuitous and contingent, and that these and other related social changes, such as the growth of bureaucracy, potentially threaten liberalism. Politically united against traditional and hierarchical societies, liberals have differed, therefore, over whether liberalism requires various kinds of political support, such as the state regulation of markets, or merely the absence of any interference by either the state or others to the spontaneous and autonomous social activities of individuals. Meanwhile, critics of liberalism have either blamed it for all contemporary social ills or regarded it as a transitory phase to be replaced by superior forms of social organization. Liberalism has featured in social science in correspondingly divergent ways: as the 'natural' value system of modern societies, as a historically and culturally specific phase of social development, and as either pernicious or expressive of basic human goods.

Liberalism Defined

For analytical purposes, it is convenient to break liberalism down into its philosophical, social, and political components, though these form a package that different liberals have interpreted in diverse ways.

Liberal Philosophy

At a philosophical level, liberals seek the maximal equal liberty possible for all individuals to rationally and freely choose and realize their various projects and preferences without interfering with each other. This position draws together the concepts of equality, liberty, individuality, and rationality in a distinctive way. Liberals value equality in the sense of denying that anyone is the natural subordinate of others. This view does not entail regarding people as the same, but merely that everyone has equal moral worth. Instead of seeking equality of outcome like certain socialists, liberals simply desire that all should have an equal opportunity to deploy what talents they do possess on the same basis as everyone else. Their attachment to liberty follows from this interpretation of equality and its implicit endorsement of the moral primacy of the individual. Among moral equals, individuals should be allowed to pursue their own good in their own way to the extent that is compatible with a like liberty for others. Finally, as rationalists, liberals believe that individuals should behave in a coherent and consistent manner and that decisions in the public domain should be open to critical scrutiny and amendment and capable of attaining the reasoned assent of those they affect.

Though liberals share a moral ethos and broadly agree on the conceptual relationships among liberalism's core values, they offer very different interpretations of them reflecting a wide variety of epistemological and ontological perspectives. Thus, liberals include methodological individualists such as

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93070-8

Adam Smith or Herbert Spencer and holists such as Emile Durkheim, materialists such as John Locke and idealists such as T.H. Green or Benedetto Croce, utilitarians such as J.S. Mill and natural rights theorists such as Tom Paine, abstract universalists such as Kant and historicist relativists such as Herder, and so on. Moreover, their main practical differences stem less from these considerations than from contrasting social visions and political judgments. Though individual thinkers naturally relate these last to their particular metaphysical and methodological views, the connections between them are far from clear-cut. Similar theoretical perspectives often generate quite different practical stances, while thinkers of quite diverse theoretical positions may often be in substantial practical agreement.

Liberal Society

Historically, the most significant social influence on the formation of liberalism was the passage from feudalism to capitalism from the sixteenth to the nineteenth century. This fueled the liberal attack on ascribed status and its commitment to equality of opportunity. The closed feudal order of inherited rights, with its hierarchical system of aristocratic privileges, was to give way to an open and egalitarian capitalist order in which an individual's social position and success supposedly mirrored his or her ability and effort – a way of life they felt was best realized in a free market economy.

Some contemporary liberals and many of liberalism's critics regard the ethos resulting from such social origins as essentially materialist, instrumental, and egoistic. Traditionally, however, liberals have been extremely wary of such attitudes and have sought to avoid them. The liberal conception of economic behavior emerged from the experience of the entrepreneurs, traders, shopkeepers, and artisans of early capitalism and invokes the image of an idealized market order in which rewards are closely linked to effort. This linkage was codified in the labor theory of value and, in the British and North American context at least, drew additional support from the religious beliefs of certain Protestant sects that encouraged industriousness as a mark of salvation. The market also acts as a discovery mechanism, with competition and the profit motive weeding out bad practices and poor products while stimulating the search for new processes and commodities, and so promoting the progress of society.

Liberals have disagreed, however, over how far a policy of *laissez-faire* can secure these advantages and doubts have grown as capitalism has taken on a more corporate form. Most have accepted the need for some regulation to protect the market against itself and maintain its freedom – such as antitrust and monopolies legislation. Others have sought to distinguish between the economic and social disadvantages that individuals are responsible for and those they are not, supporting quite extensive unemployment insurance and state-supported training schemes, for example, to get the unintentionally out of work back into jobs. Finally, liberals have always acknowledged certain public goods will be badly provided or even neglected by market mechanisms, even if some have believed state provision could employ market elements such as competitive tendering – defense and certain infrastructural goods, such as lighthouses, were the classic cases. Clean air, education, and a health service serve as more recent and contentious examples.

Liberal Politics

The political face of liberalism follows on from the philosophical and social elements outlined above, but was additionally influenced by the wars of religion and the rise of modern science in the sixteenth and seventeenth centuries, which fueled calls for religious toleration and the related belief in rationalism and the moral equality of individuals. Along with the shift from social structures based on status to contractual relations among civic equals, these commitments led to the demand that politics reflects liberal principles. The state, like society as a whole, came to be seen as a voluntary association held together by the mutual consent of its members rather than the ties of deference to social superiors – a conception of political order summed up in the theory of the Social Contract.

The basic components of a liberal political system were established in the wake of the British, American, and French revolutions of 1688, 1776, and 1789, respectively. All three gave rise to new constitutional settlements and bills of rights. Two criteria informed these arrangements. First, laws were to be framed and applied impartially and universally. There were to be no special exemptions for particular groups, such as clerics and nobles, as in the past. Second, the laws were to guarantee to the greatest extent possible the equal right of each individual to pursue their own plan of life. For the majority of liberals, the most basic rights in this respect were traditionally the rights to private property and freedom of belief. These rights were essential to their understanding of the virtues of the market mechanism and of toleration, which they regarded as the embodiments of the new ethos.

At the heart of liberal politics is a distinction between the state and civil society (*see* State and Society: History of the Concept). The purpose of the state is to facilitate social interaction rather than to substitute for individual initiative through state control of social institutions. The latter is the mark of dictatorships in liberal eyes. However, social liberals nevertheless believe that economic intervention and state provision of certain social goods can have an enabling role, though market liberals contend that such steps undermine liberalism. Liberals are also often said to favor a related distinction between the public and private sphere, allowing behavior in the latter they would ban or restrict in the former. However, this distinction has never come out cleanly. To the extent liberals do distinguish between the two, it is as a corollary of their views of the state's role in regulating society. The marriage contract, for example, offers a quintessential liberal device of a public character with a clear impact on private behavior. Just as liberals of different hues dispute the degree to which workers are free to sell their labor and the extent to which a valid contract implies certain standards of pay and conditions, so they have also debated whether and in what ways the marriage contract constrains the behavior of couples and grants women, in particular, rights to common property and protection against rape and abuse.

We have already disputed the view of liberalism as promoting possessive individualism in the socioeconomic sphere. A related objection contends that liberals advocate

subjectivism, skepticism, and relativism in the political sphere, with all views treated as little more than personal opinions. However, the liberal insistence on the individual's right to follow his or her own path does not entail regarding all ways of life as equally valuable. Drawing on the experimental method in modern science and the Protestant defense of freedom of conscience, liberals contend that truth and morality emerge through individuals being allowed to call into question accepted doctrines and try out new and occasionally eccentric or potentially offensive pursuits. Ideas have to be tested for their validity, while personal virtue only comes from our taking responsibility for our lives. For the state or any group to paternalistically impose its views on the rest of society risks falling into dogmatic error, demoralizes the population, and produces stagnation. Individuals must be able to make mistakes so that they can learn from them and emerge morally and materially improved.

Nevertheless, liberals have seen no need to tolerate the 'intolerable,' defined as views that are incompatible with treating others as moral equals. Some critics have regarded this position as inconsistent with liberalism's claims to openness. Yet, certain limits are clearly implicit in liberalism and would otherwise render it incoherent. However, where exactly these boundaries lie and their legitimacy and justifiability are more contentious matters. Liberalism has been accused of a gendered, imperialist, and Eurocentric bias, and historically this has often been the case, albeit to differing degrees and with certain important if qualified exceptions such as J.S. Mill's attack on the *Subjection of Women*. How far gender and multiculturalism remain a blind spot is less clear. Many contemporary liberals maintain that multicultural, gay, and feminist demands for recognition and respect, like other appeals against unjust discrimination, implicitly invoke liberal norms of equality and tolerance. They have simply revealed these principles to have a broader application than certain past liberals had appreciated.

The complexities of the liberal position emerge when we consider their ambivalent view of democracy. Liberals have recognized that democracy offers a means for holding governments to account, obliging policies to be justified and improved through critical debate, and allowing politicians to be peacefully removed when they prove incompetent, biased, or corrupt. However, past liberals sought to limit political citizenship to those with the intellectual attainment and economic resources they believed were required for 'independent' rational decision-making – criteria that usually had the effect of ruling out workers and women. Even so, liberals worried about the 'tyranny of the majority' as represented by an irrational and dependent mass, whose votes could be bought by unscrupulous populists willing to pander to their prejudices and interests. As a result, liberals have tended to insist on the need for constitutional safeguards to protect liberal values from being overturned by democratic decisions.

Liberalism and Modern Society

Social scientists have seen liberalism either as an inherent and defining characteristic of modernity or as a threat to it. Among the first camp, moreover, there are those who see it as symptomatic of modernity's ills rather than its advantages, identifying liberalism with a possessive individualism that is not only antisocial but antisociological as well.

Liberalism as the Ethos of Modernity

The view of liberalism as the ethos of modernity was best expressed by British social scientists such as Adam Smith, Herbert Spencer, J.S. Mill, T.H. Green, and L.T. Hobhouse, and to a lesser extent French thinkers such as Benjamin Constant, Francois Guizot, and Emile Durkheim. For these thinkers, liberalism's philosophical commitment to expanding equal individual liberty was underwritten by a theory of social evolution whereby potential conflicts between different liberties would be harmonized. This latter thesis idealized the market relations between small-scale entrepreneurs characteristic of early capitalism. These were taken as a model of a meritocratic society of self-reliant and responsible citizens, who freely contract with each other for mutual advantage. Liberal politics was conceived as the superstructural products of these social and economic changes. Freedom, reason, morality, and progress came in this way to be identified, with an optimistic account of social development supporting an implicitly ethical naturalist philosophical belief in the compatibility of different forms of self-realization.

Adam Smith's doctrine of the 'invisible hand' of the market and Herbert Spencer's characterization of the 'industrial' form of organization as realizing the 'law of equal freedom' offer classic examples of this position. The first was a product of the commercial society of the eighteenth century, the second of the early industrial age of the 1840s. By the late nineteenth century, the concentration of capital and the rise of organized labor had made liberals rather less sanguine about the inevitability of their vision. To the dismay of Spencer and other adherents of the earlier 'classical' liberalism, liberals began to envisage a more proactive role for the state in sustaining favorable social conditions. T.H. Green and L.T. Hobhouse, for instance, saw policies such as factory hours regulation and unemployment insurance as mechanisms for promoting freedom of contract and freeing individuals from certain structural constraints. Importantly though, both saw the state as reducing the mutual interferences between individuals and fostering autonomy. In a similar manner, Durkheim argued that the liberal 'cult of the individual' was inherent to industrial societies and that the modern division of labor fostered an organic solidarity between autonomous agents. However, he had to confront various commercial crises, bankruptcies, and conflicts between capital and labor, which suggested a less harmonious picture. He attributed these disturbances to contemporary societies being in a 'transitional phase' in which people had yet to fully assimilate liberal social norms. He too saw a role for the state in fostering these attitudes, with various 'intermediary institutions' serving to inform state policies as to social needs and act as a counterweight to state oppression of the individual (*see* Social Question: Impact on Social Thought).

Critics of liberalism sometimes portray this supposed relationship between liberalism and modernity in negative terms. They associate liberalism with a naturally instrumental and individualist model of human behavior, a disposition they believe is encouraged by the liberal conception of the market

and democracy. They also claim that it produces a view of social science as following the physical sciences by elaborating general laws of social development on the basis of various constant human passions. Some commentators have even argued that it were only radical and conservative opponents of liberalism who appreciated the distinctiveness of the human sciences by noting, respectively, how human behavior was modified by social structures and culture, and the capacity of individuals to interpret and evaluate circumstances in different ways. At best, liberalism results in a positivistic bourgeois ideology that ignores the impact on human thought and action of material conditions and productive forces, historically evolving communal traditions and conventions, and the possibility for reflective criticism. Thus, liberalism is associated with certain behaviorist versions of political science and economics, but not with sociology or anthropology. These arguments result from a highly selective and tendentious reading of the liberal tradition whereby, for example, De Tocqueville becomes a 'conservative,' Durkheim either a 'conservative' or a 'socialist,' and Herbert Spencer, read as an advocate of egoistic possessive individualism, becomes the exemplar of liberal social science. The liberal tradition, however, is much more diverse than this caricature, both methodologically and substantively. The vast majority of liberals distinguished respect for 'individuality' from 'egoism' and even positivist behaviorists, such as J.S. Mill, appreciated that autonomy only flourished given certain material conditions, cultural values, and economic structures and played a part in its turn in how these were fashioned in the future. This awareness of the social and historically contingent character of liberalism is no more evident than in those liberals who saw it as being undermined by modernity.

Liberalism as Threatened by Modernity

The threat posed to liberalism by elements of modernity was especially evident in countries such as Italy and Germany, where a modernizing economy and society went along with fragile and incomplete liberal regimes which ultimately succumbed to fascism. The challenge these developments posed for liberal social science is powerfully illustrated by the 'frustrated' liberalism of the Italian Vilfredo Pareto and the 'disenchanted' liberalism of Weber. Though commonly categorized as sociologists, their work ranges over the whole gamut of the social sciences, covering economics, politics, and, in Pareto's case, social psychology. Pareto was in many respects a sophisticated exponent of the instrumentally rational actor model of liberal individualism and was initially a strong advocate of both *laissez-faire* economics and a libertarian and democratic politics. However, he became convinced that what he called 'logicoexperimental' thinking was the exception rather than the rule. Instead, most conduct was 'nonlogical' and arose from certain common psychological dispositions of either a conservative or more inventive kind. Politics simply consisted of the manipulation of these psychic states, a process that had been greatly aided by contemporary mass democracy. The electorate was too large and poorly informed and the decisions needed too numerous and diverse one for rational debate to be possible. Democracy simply allowed populist leaders to legitimize their rule via emotive appeals to a popular will that was largely of their own making. He even briefly supported fascism as a possible way of breaking free from this system and establishing a liberal market order from above.

Weber, by contrast, offered a more historically and sociologically nuanced account of similar phenomena. He disputed that economic development per se fostered liberalism or that liberal values could be justified a priori. Liberalism's apparent basis in natural law had been historically contingent, reflecting the peculiar social and political experiences of early modern Europe outlined above. Not only was this constellation of factors unlikely to reappear but even within established liberal regimes, liberalism was threatened by the spread of economic instrumentalism, bureaucratic rationality, and corporate organization resulting from the further development of capitalism. The chances of liberal democracy being established in societies such as Russia, which had not benefited from the earlier favorable historical experiences, were minimal, therefore. Quite different cultural values were likely to shape the modernizing processes of such societies, as indeed has occurred throughout Asia, where capitalism has by and large taken a nonliberal form. Meanwhile, in already existing liberal societies, the autonomous action characteristic of liberalism was possible only for the political leaders and entrepreneurs who controlled and gave direction to the various political and economic administrative structures that govern our lives (*see* Modernity).

Most contemporary liberal thinkers regard Weber as too pessimistic and many believe liberal values can be justified on grounds distinct from their historical and social origins. However, the possible disjunction between late modernity and liberalism, on the one hand, and the search for liberal foundations that appeal to reasons that ought to be accessible to all and so compatible with a variety of different cultures and ideals, on the other, remain the prime challenges a viable liberal theory has to meet.

Contemporary Liberalism

Contemporary liberal philosophers have sought to overcome the Weberian challenge by seeking to divorce liberal principles from controversial ethical, epistemological, and ontological viewpoints. They argue that the chief advantage of liberal theories of the market, democracy, and justice resides in letting people holding different moral and material priorities and preferences live peaceably and profitably together. However, in spite of this agreed approach, these theorists split along the main ideological divisions of the contemporary world. The gradual electoral drift of liberals to social democracy, on the one hand, and to conservatism, on the other, has been reflected in a parallel division in contemporary liberal philosophy between social democratic and New Right, neo-liberal theorizing. I shall briefly examine an example of liberal thinking from both these camps.

Liberalism between Social Democracy and Neo-Liberalism

The major exponent of contemporary social democratic liberalism is John Rawls (1921–2002), whose *A Theory of Justice* (1972) is probably the most important work of political philosophy written in English since World War II. Rawls uses

the classical liberal device of a social contract to arrive at two principles of justice, which he believes will serve to regulate the relations among individuals within modern societies. He asks us to imagine which principles we would choose to adopt if we knew neither what sort of person we were nor the precise circumstances of the society we might be born into. All we know are certain general facts about human psychology, sociology, economics, and politics.

Rawls believes that this thought experiment, which he elaborates in great detail, will produce a theory of justice that everyone will accept as legitimate because it is untainted by any preconceptions about the worth or lack of it of particular beliefs or ways of life. Rather, we shall be drawn to appreciate the value of showing equal concern and respect to all people, regardless of their views. For, faced with the radical uncertainty of what Rawls calls the 'original position,' we will seek to arrive at principles of justice that are as fair as possible to all persons, whatever their talents or ideals might be. Indeed fairness, rather than truth or goodness, is the only acceptable criterion of modern justice for Rawls.

What then are Rawls' two principles and what kind of policies do they require for their realization? According to the first principle, the state must provide the most extensive system of equal liberties possible. All individuals must enjoy the greatest degree of liberty consistent with the enjoyment of a like liberty by everyone else. According to the second principle, there must be equal opportunity to obtain positions and status in society, regardless of color, gender, or creed. To help achieve this goal, each person is to have an equal share of wealth *except* when an unequal distribution would improve the welfare of the least well-off in society, by providing incentives that encourage people to work harder and produce more in ways that raise the living standards of everyone. Even so, a progressive taxation policy would be necessary if the trickle-down effect failed to produce any benefits from this greater affluence for those at the bottom of society. Like earlier social liberals, such as Hobhouse or Durkheim, therefore, Rawls tries to combine the liberal values of liberty and equality with a concern for social justice tempered, in characteristic social-liberal fashion, by the requirements of efficiency. Unlike earlier social liberals, however, he has sought to dissociate his argument for these policies from the traditional liberal ethos and metaphysics.

Three years after Rawls' book appeared, Robert Nozick (1938–2002) published *Anarchy, State and Utopia* (1974), defending the market and a minimal state and criticizing any form of welfarist policy on libertarian grounds. He argues that any attempt to redistribute resources or to intervene in the economy involves an illegitimate attempt to use people to further some social purpose with which they may not agree. In his view, the advantage of the market is that it reflects no particular conception of the good, the resulting distributions being merely the unplanned consequence of numerous exchanges among individuals. So long as nobody is deliberately and physically coerced into exchanging goods or selling his or her labor to another and there are no legal barriers discriminating against who can apply for jobs or what can be sold, then the liberal criteria of liberty and equality have been satisfied and the market system can be judged as fair. The inequalities that result from its operation follow no strict pattern. Those who do well cannot be said in any absolute sense necessarily to deserve or merit their success – they have merely been fortunate to be born to rich rather than poor parents or to have had talents that proved to be marketable. Their entitlement to their wealth rests simply on the right not to be interfered with by others, for what we have obtained through transactions which honor the right of each and every individual not to be coerced is rightfully ours. As he puts it, governments have no legitimate grounds for meddling with capitalistic acts between consenting adults.

Just as Rawlsean social liberalism has been taken up by social democrats, so New Right theories such as Nozick's, which offer a neoclassical liberal defense of the free market, have been taken up by conservatives. Indeed, his argument does contain a strong conservative bias, since it rests on an explicitly historical view of justice based on the pattern of distribution that evolves through market exchanges over time. However, Nozick never claims to be a conservative and others with similar views, such as Hayek, explicitly reject the label. As Roger Scruton has pointed out in his book *The Meaning of Conservatism*, Nozick's right-based argument is in direct opposition to the Old Right emphasis on "the web of obligations by which citizens are bound to each other and the state." Moreover, although his theory accords best with *laissez-faire* capitalist society, he draws on the anarchist and Utopian traditions to suggest that it could be compatible with any form of social organization provided it was voluntarily entered into. In common with other contemporary liberal thinkers, the central commitment of his theory is to a pluralist framework which provides scope for people to live according to diverse conceptions of the good.

How convincing are these two versions of liberalism? Once we leave the Rawlsean 'original position,' for example, and discover who and where we are, what would motivate us to adhere to the two principles if they appeared to conflict with our most important ideals or interests? Surely, only someone who had swallowed a good dose of liberalism in the first place would feel at all inclined to distance themselves from their cherished beliefs and social and material attachments in the way Rawls' theory requires? Similarly, Nozick offers no reasons for why we have certain rights rather than others, while his defense of Locke's 'labor mixing' theory of property ownership rests on a dubious metaphysics. As so-called left-libertarians, such as Hillel Steiner and Philippe van Parijis, have noted, if there is no predetermined distribution of land and no reason to believe that – all things being equal – some people deserve more property than others, it makes sense to think of resources as commonly owned. There is no reason to think that the first use gives an entitlement to ownership. If so, land remains in common and those who use it owe the rest a 'rent.' Nor is it at all clear that either theory will be pluralist in outcome. In other words, neither theory seems to work unless it invokes some of the ethos of earlier versions of liberalism. To the extent that this ethos has proved inadequate, then so are these versions of liberalism.

Liberal Ideals in a Nonideal Society

For all their philosophical sophistication, such theories seem politically and sociologically naive, greatly exaggerating the

possible independence and opportunities available to individuals within complex societies. The division of labor, international markets, the organizational structures of modern economies – from large-scale bureaucratic states to multinational corporations and financial and political institutions such as the IMF and the EU – these and other factors make theories that take as their starting point the autonomous individual agent, capable of making his or her way in the world through talent, effort, and voluntary agreements with other individuals, appear unrealistic. As a result, liberal philosophy has shifted from offering an idealization of the modern social reality to providing an ideal critique of that reality.

Rawls' last two works that followed up *A Theory of Justice – Political Liberalism* (1993) and *The Law of Peoples* (1999) – in many respects mark the transition between these two forms of liberal theorizing. In the first work, he made plain that his arguments were designed for liberal democratic states and sought to outline their underlying logic and the public attitudes and reasoning that citizens and public officials needed to adopt for them to work legitimately. He also suggested that justice should be seen primarily as political and secondarily as social and economic – a means for fairly resolving the many disagreements citizens have about how to shape their collective life. In the second work, he offered a sketch of a theory of international justice that controversially both took the state as the main actor in international affairs and sought to accommodate 'decent' but nonliberal democratic regimes.

These works have been heavily criticized by many who admired *A Theory of Justice* and had regarded it as a theory of universal and global scope and that applied to individuals rather than to political communities. Rawls' response was that he had aimed at a realistic Utopia – a vision that seeks ideal principles for a nonideal world, not least because of the morally and rationally imperfect people who inhabit it. Nevertheless, some believe these works made too many concessions to the status quo, giving too much leeway to cultural differences and social inequalities in particular. They contend that liberal ideals should produce changes in the world rather than simply understanding it, and have sought to deploy his arguments to advocate major reforms to the state system to address global poverty and climate change, among other issues. However, others believe his realism did not go far enough. They suggest that a realistic liberalism takes the inevitability of political conflict as its core, and that a global egalitarianism has to accommodate cultural and social differences, especially when embodied within existing self-governing political communities.

Conclusion

In certain respects, liberalism has become a hegemonic political language. Even those who do not espouse liberal values have a tendency to invoke them by appealing to toleration, equality, or rights when seeking a hearing for their views. Yet, the pervasiveness of liberal discourse also proves problematic. On the one hand, it produces a plethora of liberalisms so that it becomes difficult to identify a coherent and generally accepted liberal program. On the other hand, liberalism can seem either as an ideal at odds with the realities of contemporary societies, and as such either unrealized or possibly unrealizable, or as providing current realities with either a justified or spurious legitimation. Liberals and their critics can be found espousing all of these positions: indeed, even the same individual may voice elements of each of them with regard to different issues. Yet, the continuing relevance and interest of liberalism rests on its dual character as both the ideal and the reality of modernity, at once its best defense and critique. To be convincing, it has to be able both to understand and to change contemporary societies – the challenge confronting liberal theorists is to show that it can be both real enough to do the first and ideal enough to achieve the second.

Liberation Theology in Social Work

Abstract

The notion of empowerment has been a common outcome of both liberation theology and anti-oppressive social work and provided models for practice. These liberating movements rooted in the 1960s represented a challenge for traditional practices within the Catholic Church and social work practice, respectively. The concept of hope crosses both perspectives relating hopelessness and powerlessness, in a positive causal relation whose end point is the cessation of oppression. The aims of liberation theology and anti-oppressive social work are to promote emancipation by identifying the structural conditions wherein the roots of oppression lie.

Liberation Theology and Social Work: Anti-Oppressive Concerns Are Common Grounds

The notion of empowerment has been a common outcome of both liberation theology and anti-oppressive social work and provided an important element in models for practice. These liberating movements became rooted in Latin America, during the decade of 1960s and represented a challenge for traditional practices within the Catholic Church in the first case, and within the social work practice in the second. Both models have had an enduring legacy in developing forms of social involvement and political engagement.

The concept of hope encompasses both perspectives and has established a significant relation between hopelessness and powerlessness, especially in promoting in a positive causal relation in ending oppression. The aims of liberation theology and anti-oppressive social work are related to promoting emancipation and identifying the structural conditions wherein the roots of oppression are embedded. Therefore, both perspectives conduct a process of conscientization that increases awareness about the condition of victims in a social, economic, and political system that produces oppression. The process of conscientization requires collective support to realize that oppression is not an individual problem but a shared one and to set up strategic agendas promoting social change. The related concepts of hope, empowerment, and liberation should be kept in mind when studying liberation theology and social work.

Liberation Theology as Practical Hope for the Oppressed

Liberation theology meant practical hope for Latin America's poor communities seeking to overcome human hardships, because emancipation could be realized in reality through liberation and not by expecting a Messiah (Scherer-Warren, 1990). Traditionally in Latin America, the Catholic Church had failed to implement its role of liberating oppressed peoples, primarily because it became affiliated to those in power. However, with the growing importance and defense of social equality and equity in the 1960s and 1970s, the Church began to advocate for social justice for marginalized or oppressed peoples (Noelliste, 1995; Smith, 1991); as Levine stated "once seen as a cultural reservoir for apathy and fatalistic resignation, religion, above all the Catholicism of popular classes, now commonly appears synonymous with solidarity and resistance to injustice and repression in cases other-wise as different as Brazil, Chile, or El Salvador" (1988: p. 242).

The emergence of liberation theology was a reaction to the politics and economy of the late 1960s and early 1970s, which included repressive regimes and vast capitalist expansion in Latin America (Noelliste, 1995; Smith, 1991; Levine, 1988; Boff, 1980). The Second Vatican Council ended by concluding with a socially oriented doctrine, especially for people in what was then called the Third World who were defined as the proletariat of contemporary humanity. This change in the Catholic Church's focus and newfound interest in social justice brought many new people into the Church, and became very popular within the sociopolitical context of the Latin America of the time. The new view has been defined as based on a critical sociostructural analysis, anchored on Marxist categories of class, conflict, and exploitation where an explicit effort at analysis aimed to understand the social context through the eyes of poor people and reducing distances between the Church and average believers (Levine, 1988: p. 243).

The social context then prevailing in Latin America was one of the general crisis affecting the economical, social, political, and ideological spheres. The region was becoming an object of development for industrialized countries, and Latin American peoples became concerned with the levels of exploitation and marginalization that they were living within because development was being achieved at the expense of poor people while benefiting traditional elites and partners of international companies (Smith, 1991; Boff, 1980). There was awareness about the contradictions produced by political and economic policies. On one side, there was capitalist development, and on the other, there were several populist measures involving marginalized groups that had suffered failures similar to those of the Alliance for Progress (1961–69). These capitalist initiatives impoverished a high proportion of the Latin American population who became doubly affected by tragedy through the repression exercised under the emergency powers of the military dictatorships that had assumed control in many countries (Dodson, 1979; Boff, 1980; Gutierrez, 1984; Silva, 2009).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28051-3

An awareness of their conditions gave rise to social discontent. With the support of pastoral organizations from universities and grassroots organizations, these people became engaged in the implementation of other strategies aimed at raising higher levels of consciousness about inequality and oppression. The results were the development of the Basic Educational Movements and Christian grassroots communities that were composed of lay people and nuns. These movements were strongly influenced by the Brazilian educator, Paulo Freire (1970) who advocated the development of critical consciousness to facilitate the process of liberation. The Second Vatican Council (1962–65) gave institutional support to these movements that increasingly faced rejection from their official governments. Consequently, some of these became militarized to fight social movements and keep control of government. The Second Vatican Council also contributed to reflections about a faith-based liberation praxis that searched for and validated social justice, participation, dignity, and fraternity.

Classical writers of liberation theology, like Boff (1978) and Gutierrez (1984), when analyzing the Latin American situation, made the distinction between 'developing countries,' 'countries in development,' and 'developed countries.' These definitions favored the last category and stated a country would be considered a developed country only when it reached a specific income per capita, degree of consumerism, a determined number of vehicles, hospitals, schools, libraries, life expectancy, and other variables that defined it as a developed country (Boff, 1978). Thus, it would only be possible to be considered a developed country by adequately conforming to the culture and expectations of the Western countries then dominating the world. Underdeveloped countries were categorized as dependent countries. These countries had started to incorporate the presence and expectations of the dominant countries both internally and externally in the hopes of becoming a developed country. However, by allowing the domination or guidance of developed countries, they became dependent upon those, and thus laid the grounds for further oppression and exploitation (Gunder-Frank, 1969).

These types of relations explained that dependency theory became one of the underlying explanations of the subjugation experienced by people in Latin America who were living under an imposed dependency emanating from the center poles of development in relation to the peripheral ones. These ideas generated controversy and broke the notion of interdependency among countries, when the oppressive character of the labor relations in Latin America were exposed and revealed the suffering of its workers and how this impeded real social progress and transformation. Furthermore, there was an acknowledgment of the causal relations between opulence and poverty. Oppression represented an historical condition for Latin American peoples, and liberation theology became a legitimate vehicle through which channel the liberation demands of oppressed populations (Boff, 1980; Ellacuría, 1989; Gutierrez, 1990). There have been some critics to this notion of dependency, including those considering it reductionist because it turned people into homogeneous passive victims. Dodson (1979: pp. 208–209) has claimed that dependency theory constituted an overreaction by most the theologians of liberation because their awareness of dependency theory was limited, reducing it to a simplified and homogeneous understanding of Latin American realities when the region is characterized by great complexity and diversity in its socioeconomic and political conditions.

At that time, the Encyclical, Popularum Progressio (1967) was especially directed toward Latin America to promote the overcoming of injustice and marginalization. In this scenario, the Episcopal Council of Latin America was created. Several meetings of Latin American Bishops were celebrated, one of them taking place in Medellín, Colombia (1968). This meeting reinforced the process of radicalization of the Latin American Church, a process that culminated with the third meeting of Latin American Bishops in Puebla, Mexico (1979) which also kept its strong commitment with a Catholic Church that engaged with oppressed peoples.

Liberation theology focused not only on critically analyzing reality, but also on transforming it. Transforming reality was made possible through the methodological originality of this theology, namely, its claims for transformative action through praxis. This praxis should advance toward salvation understood as a process of integral liberation including the economy (liberation from starving) and politic (liberation from marginalization); culture (liberation from analphabetism or illiteracy and ignorance) and pedagogy (liberation from depersonalized dependency); and religious (liberation from traditional understanding of sin and rejection of the Historical plan of God) (Silva, 2009: pp. 157–158; Alberigo and Jossua, 1987: p. 92).

The Bishops meetings produced clarity about the meaning of liberation theology and its methodology which was composed of three fundamental steps. The first was to ascertain a reflexive practice about reality (moment to see); the second was to enlighten these practices with a theological thinking (moment of judgment); and finally the moment to set up the tracks for pastoral action (moment of action). Under these movements, the Second Vatican Council appeared enlightened by the transformation of Latin America and not the reverse.

The social and political effervescence produced by this consciousness among oppressed and marginalized peoples ended in 1968 when the initiative was assumed by several military governments in Latin America, most of them highly repressive. Many pastoral communities suffered repression, torture, and prison. Repressive measures were also visited upon secular people, as well as nuns and priests, like the case of Monsignor Romero in El Salvador, who suffered a tragic demise, because he spread liberation beliefs and practices to the highest levels of the Church hierarchy (Katra, 2012: p. 37). Similar situations occurred in other countries because ruling oligarchies were threatened by the liberation church. Their responses became increasingly punitive and were sometimes expressed as "obscene repression like the one exerted against the progressive Church in Guatemala, with the martyrdom of priests, nuns, and lay workers; the forced exile of the Maryknoll and Jesuit orders; the official support for rival Protestant groups; and the de facto disappearance of pastoral agents from some regions" (Katra, 2012: p. 37). This situation gave a new perspective to the theology of liberation and the theology of Cautiverio, concept that was understood as confinement, captivity, which emerged as a new moment of reflection wherein the interest of national security disguised the defense of capitalism (Berryman, 1987).

The Theology of Cautiverio emerged as many dictatorships were installed throughout Latin America: Brazil (1964), Bolivia (1971), Uruguay (1973), Chile (1973), and Argentina (1976). Previous military governments turned toward right-wing ideologies, like Peru (1975) and Ecuador (1976), and repressive governments continued in power in most parts of Central America, only Mexico, Colombia, Venezuela, and Costa Rica stayed under formal democratic mechanisms, and even these governments used hard measures of repression (Silva, 2009). Whereas prior to the oppressive regimes, the Catholic Church and its members could publicly fight inequalities, after the military coups in these countries, they had to fight and try to change things from with the surveillance of the dictatorship and its repressive regulations. Cautiverio was related to liberation theology; the difference, however, is that its focus lay on dependence instead of freedom. "The Theology of Cautiverio differentiates between being free from and being free for; being free from represents a confined situation, whereas being free for assumes having control over the situation" (Boff, 1980: p. 119). Practicing under a military dictatorship made the latter option extremely difficult.

Therefore, the Theology of Cautiverio was not only social, political, and economical, it was "the embodiment of a deeper deviation of man that reaches the fundamental sense of being and living as understood by [the] power-conquest-domination [nexus], engrained in oppression, repression and a global[ly] confined regime. It is history told by those who triumphed by force, of those on top, of those who were able to assume the decisive power over others. Nobody talks anymore about lost hope of those humbled and assassinated" by the brutality of their own rulers (Boff, 1980: p. 179).

According to Boff (1984), Gutiérrez (1970), and Scherer-Warren (1990) to face this crisis, only five lines of theological-pastoral actions were provided by the Church and promoted in the different meetings, from Medellín (1968) to (PUEBLA, 1979: p. 1220).

Preferred Action for Poor People

There was a crucial change when the Catholic Church no longer had an interest in blaming poor people. It had become a Church with the poor, thereby implying a more active role for poor people in defining the pastoral action of the Church and assuming that the condition of poverty was caused by structural factors based on economic, social, and political arrangements. "This change will not be truly honest. At least it goes along to a change of personal and collective mind-sets about the ideal of a human dignity and human happiness, all of which dispose people favorably toward conversion" (PUEBLA, 1979: p. 1152).

Integral Liberation

This notion overcame the idea of liberation being restricted to the spiritual sphere and includes a wider understanding that is a practical, political, and social action to enhance the space of freedom among poor populations.

Foundational Christian Communities (Known as Ecclesiastic Grassroots Communities)

The people, individually and collectively, build a plural society, and the Church acknowledges that they are agents of a process of general conscientization about common social responsibilities and as communities that bring the voice of people into transforming the Church (PUEBLA, 1979: p. 1220).

Human Rights as God's Rights

Human rights were to be protected by the Catholic Church, especially at a historical moment when people's movements were politically restricted and their rights were violated.

Preferred Action for Young People

Young people represented more than half of the total of Latin American population at that time. The Catholic Church trusted these young and saw in them its future hope; Latin American young people had the true potential for present and future evangelization because they could be used to mobilize the social corps and particularly the ecclesial corps and renew its structures and populations (PUEBLA, 1979: p. 1186).

The methods used to generate awareness among the oppressed peoples of Latin America (poor people, women, children and young people, black people, and indigenous peoples) included the action of bringing together people who suffered the same type of oppression to form a group identity, encourage the rediscovery of their dignity, and stimulate their confidence in change (Scherer-Warren, 1990).

Liberation theology was an answer to modern culture, a revision that acknowledged the main victories of modern thought: consciousness and through autonomy, religious freedom, secularization, and the historicity of humanity, which means "a desire to read the signs of the times, valuing and learning from the world in which the Church is intimately and inextricably entangle" (Levine, 1988: p. 244) and therefore, in search of the meaning and direction of historical change.

The Second Vatican Council allowed the vision of the Catholic Church as part of the world and not separated from it, which meant the search for recovering the dignity of the human person and transforming oppressed peoples into agents of their own history, process that happens through the interpretation of everyday life and not through the obedience to pre-existing orders. This understanding gave support to a plurality of interpretations enriching political and social action and producing results in the apostolic work of the Church and in the commitment to civil organization for human rights, as well as in the engagement in actions aimed at promoting radical changes. Therefore, liberation theology offered a hope in the power of collective organization to promote change for a better society, becoming a basis for social action and political commitment.

A contribution from liberation theology has been the consideration of the insight into reality brought by people; it shows a hermeneutical position that appreciates the "value of ordinary experience as a guide to reflection and action" (Levine, 1988: p. 254), where the method for inquiry values an interpretive discipline, framed by the particular historical

context being explored. Therein lies a fundamental commonality between liberation theology and the understanding of social work as a profession in search of an anti-oppressive world.

Anti-Oppressive Social Work: Fighting the Roots and Effects of Social Oppression

Social work in the 1960s questioned its professional practice as one profoundly influenced by society's economic and political forces, and marked by apathy in response to inequities caused by structural sources of oppression over excluded groups in society. These critics gave origin to Structural Social Work in Canada (Lundy, 2004; Moreau, 1989; Mullaly, 2007), and in Britain, it began as Radical Social Work (Bailey and Brake, 1975) which brought social workers in close proximity to service users through action-research and attempts to form alliances with them and to develop new forms of practice. Although this quickly moved to Marxist Social Work (Corrigan and Leonard, 1978), this approach was found lacking for ignoring crucial social divisions such as 'race' and gender and gave rise to alternative theories and paradigms for practice. Crucial among these were Antiracist Social Work (Dominelli, 1988, 1997, 2008), Feminist Social Work (Dominelli and McLeod, 1989; Dominelli, 2002b), and Anti-oppressive Practice (Dominelli, 2002a). In Australia, these critiques were elaborated further through postmodernism and what became termed as Critical Social Work (Fook, 2002).

Structural social work, like radical social work and its successors, was conceived of social work within a critical tradition concerned with the broad socioeconomic and political dimensions of society that disrupted egalitarian relations among individuals and communities, and aimed to promote the emancipation of oppressed populations and fight structural barriers that affected the living conditions of service users. Structural and radical social work rejected traditional professional views and definitions of practice. Similar to the demand of liberation theology in regard to eliminating its top-down and hierarchical relations with people, and becalming involved in more dialogical and collaborative relationships, structural social work assumed that similar actions would help the process of advancing institutional and structural change within social services (Moreau, 1989).

The antiracist, feminist, anti-oppressive, and critical approaches to social work introduced a dominant concern with ensuring the realization of social justice and human rights as an integral part of their critique of structural barriers to equality and in providing the foundation for paradigms of practice that were led by service users' participation in what was developed. Thus, these approaches appealed to "social work's value base" (Dominelli, 2002a: p. 4) and sought to link personal troubles to public issues as a way of undermining structural barriers to liberation for all marginalized and disenfranchised groups. Thus, all these perspectives shared an understanding of the relation between individual action and social structures and the impact each one has on each other, and demanded a permanent critical self-examination that allowed advancement toward change that reshaped mainstream social services and probation provisions (Dominelli, 2002a).

Radical social work as proposed by Bailey and Brake (1975: pp. 9–10) acknowledged the need to understand the position of oppressed people in the context of the social and economic structures they lived in, and like liberation theology was based on a socialist perspective that challenged the traditional professional perspective that supported ruling-class hegemony to argue that social work should assist people to understand their alienation in terms of their oppression and build up their self-esteem (Bailey and Brake, 1975: pp. 9–10).

Corrigan and Leonard (1978) tried to promote Marxist social work and emphasized that social workers and service users should avoid experiencing their social world from an individualized perspective. Instead, they argued for collective action based on solidarity between social workers and service users though group action. It sought to build on the existing richness of the existing working-class movement by bringing together community political activity with collective class action through the working class movement including trade unionism to achieve growth. This emphasis on a collective understanding and support is a feature it shares with liberation theology.

Dominelli (1988, 1997, 1997b, 2008), one of the foremost educators and theoreticians in British social work, was instrumental in developing radical social work in new directions. This culminated in *Green Social Work* which introduced environmental justice as an integral part of social justice within the framework of citizenship-based entitlements and human rights. This had been preceded by *Anti-oppressive Social Work* (2002a), which built on the first engagement with an *Anti-racist Social Work* perspective, which sought to advance toward "social justice and its capacity to challenge exiting social relations through strategic collaborations with other like-minded professionals" (1997b: p. 7). This challenge for a collective and reflective action in the profession, evolved through the time, giving an account of globalization through which Dominelli (2002a, 2004) called for the enhancement social justice and well-being within the complexities of the racialization processes that focused not only on service delivery, but also on the very labor process that affected social workers themselves and their professional labor. Additionally, the theme of social justice and equalitarianism was promoted through an analysis of gender relations and the discussion of feminist social work (Dominelli and McLeod, 1989; Dominelli, 2002b). These also developed research and scholarship in the arena of feminist social work that concerned itself not only with the well-being of women, but also that of men and children, themes that others subsequently studied further. This corpus of work defined social problems as socially constructed and rooted in political practice rather than abstract theory with little relevance to the realities of life as experienced by ordinary people and marginalized groups, insights essential for emancipatory social work (Dominelli, 1997).

In search for a more complex concept of power, Dominelli (2002a) challenged binary thinking, and through anti-oppressive social work created a body of knowledge that replaced the dyad of empowerment or oppression with a continuum of power relations that moved from oppression to anti-oppression to non-oppression in complex and fluid ways that were negotiated by all those involved in particular interactions, rather than being predetermined, thus leading to

major advances in contemporary social work. Anti-oppressive practice considered the daily experience of oppression in which people lived as framed by social divisions and structural inequalities, including the oppression generated through social work practice itself. Anti-oppressive practices searched for "a more egalitarian value system concerned with reducing the deleterious effects of structural inequalities upon people's lives; a methodology focusing on both process and outcome; and a way of structuring relationships between individuals that aims to empower users by reducing the negative effects of social hierarchies on their interaction and the work they do together" (Dominelli, 1996: p. 3). Thus, anti-oppressive social work seeks to empower people and engage their consciousness and capacity to exercise agency through their interaction with others, ensuring that power was not simply the exercise of control over others, but a "complex phenomenon which is constantly negotiated and renegotiated between social actors" (Dominelli and Gollins, 1997: p. 396).

Finally, Fook (2002) and Healy (2000) espoused critical social work in Australia, highlighting advances in theorizing the concept of power with a complexity of influences that shape power relations and reduce the potential of social work to exercise power on behalf of powerless people and the importance of empowering disadvantaged people through their own agency rather than disempowering them through social labeling.

In considering reality as socially constructed and embedded in power relations between different groups of people, anti-oppressive and critical approaches to social work share a similar emphasis, with liberation theology, and promote practice that enhances the value of everyday experiences and utilizes the insight of ordinary people to critically review and critique the forms of social work practice to which they are exposed. This progressive advance of social work in identifying inputs, processes, methodologies, social relations, and outcomes to find interpretations of social reality affecting peoples' lives in a holistic manner approximates the praxis proposed by liberation theology in terms of promoting a reflexive practice about reality, enriched by a moment of judgment exerted by the oppressed population itself and finally reaching the moment of setting up action, an action that has been concerned with the fundamental questions proposed by Dominelli (1996) about what, where, when, why, who, and how social work could proceed with the aim of bringing under analysis the different elements of oppression, and promoting organizational, societal, and personal change.

Latin American social work was not indifferent to these reflections, assuming a critical perspective of capitalist societies, impelled by the movement involving the re-conceptualization of social work (Faleiros, 2011; Netto, 1976), based on a Marxist analysis about capitalism, searching for transformations of social structures, critically analyzing social work's daily practices, and questioning its servile disposition toward dominant social structures.

The contribution that anti-oppressive social work gives to the discipline is the notion of empowerment as a deliberated process whose protagonist is the person gaining power and taking over control in his or her life. This new role allows people greater access to social resources that not only favor their personal goals, but also their collective aims. Anti-oppressive practice seeks to raise critical awareness and for oppressed communities to understand structural inequalities and obstacles, contribute in the development of their capacities and social capital to increase their control and influence in society, and improve their access to social resources and their participation in social decision making.

The challenges identified by anti-oppressive social work have been acknowledged by the International Association of Schools of Social Work (IASSW) and the International Federation of Social Workers (IFSW), as both organizations have expressed as one the main concerns of the social work profession "the liberation of people to enhance well-being" (IFSW, 2002). This commitment implies a permanent reflexive practice for social workers as they engage with the constraints professionals face in relation to their different and competing loyalties when playing dual roles as helper and controller, and permanent institutional demands, frameworks, and situations that require highly ethical awareness in and responses to professional interventions (Strier, 2007).

Structural social work, as a seed for critical action in the profession, and anti-oppressive social work as an empowerment challenge for oppressed communities, had highlighted and questioned the structural origins of service users' problems and called for radical social change. Anti-oppressive social work theory is also based on critical analyses of practice relations, promoting a critical practice theory that demanded social justice in practice and policy. The achievement of these aims requires defeating the structures of oppression that are reproduced through ideological processes, power relations, and routine practices, and underpin radical social change as within sustained, inclusive, and participatory models of action. This explains Fook's claim that consciousness of a social context informed by the experience of service users becomes one of the earliest principles of a critical social work (2002). Therefore, anti-oppressive social work drives its forces toward making visible sociopolitical and economic contexts that affect individuals and develop awareness about their collective nature, as well as helping in reaching a wider consciousness and critical thinking as a way of empowering marginalized people (Lundy, 2004).

Empowerment, anti-oppression, and critical awareness emerged from social work's development as well as from liberation theology as these searched for an emancipation process at the service of oppressed people. Both movements embrace a similar mission, which is the fight against the roots and effects of social oppression. Additionally, both movements demanded political and social models oriented toward liberation and social collaboration.

Social work and liberation theology shared the emancipatory perspective as common ground, to change the structures and procedures in relating to oppressed peoples. The Catholic Church shifted from being for the poor when the liberation perspective compelled it to being with the poor. Social work's anti-oppressive practice was required to make visible the power that users have, instead of defining them a priori as disempowered. Both approaches challenged established nostrums and declared that the promised land is on earth, the question of difference was about the steps needed to transform these

challenges from a starting point of recognizing oppression to reaching an arrival point of liberation.

Challenges of a Liberating Perspective

Despite the enduring legacies of liberation theology and anti-oppressive social work, there remain conventional forces in the Catholic Church and mainstream social work contributing to the hegemony of oppressive structures including racism, classism, patriarchy, and sexism which maintain conformance toward the culture and expectations of the dominant social system.

Social work can play a significant role in resisting the interests of traditional and conservative groups that pursue their own interests against the most disadvantaged groups. Its impact could be strengthened through research guided by the principles of the anti-oppressive movements studied here: hope, empowerment, and liberation. If social work research legitimates the incidence of participatory and action research, it would value the outcomes found in studies where under-represented populations have a central role influencing the inquiry process. As Strier (2007: p. 25) proposed for anti-oppressive research, policy formation would be less controlled by those who have the power and authority 'when participants are acknowledged as experts of their own lives and capable of self-determination' and the outcomes used to benefit these participants that include formative processes of collective unity that recognize a common identity, and advance toward a more egalitarian society. One prerequisite of this process is a transformation of the power relations between researchers and participants, evolving toward horizontal relationships, as the way to understand oppressive social relationships (Strier, 2007). Such understanding will help to reduce alienation produced by the silence and invisibility suffered by excluded social groups.

Strier (2007) proposed restoring the liberating vocation of social work beyond practice by making research a core dimension of challenging dominant research patterns that can become tools for oppression. This requires the capture of silenced service user voices, the assumption of a critical stance toward social policy that emphasizes a restricted vision of what constitutes evidence-based practice and valued only as effective outcomes (Strier, 2007). In conclusion, critical research, interested in promoting liberation from oppression, hope, and empowerment needs to consider partnership, not paternalistic relationships between researchers and research subjects drawn from marginalized groups. Its results are especially relevant for Latin American societies, where the prevalence of hierarchical relations based on class distinctions act against the engagement of individuals as active agents rather than passive recipients in social action as well as in the research processes. The option for an inclusive research practice requires a defensive strategy to beat the struggle of being opposed to regular models of power and abusive relations, because the empowerment of civil society promised in Latin America is by earthly salvation through theology of liberation which had not translated easily into real power at the grassroots levels. This gives urgency for new impulses whereby to realize the material hopes and counter disillusionment among ordinary people.

Libertarianism

Abstract

Libertarianism is a largely American political movement of the twentieth century. It is also a political ideology whose main commitment is to individual liberty. Libertarianism is a species of liberalism – one which is highly skeptical of – the authority of the state, and which, at the extreme, rejects its legitimacy altogether. Two ideas are fundamental to libertarianism. First, each individual is entitled to live as he or she thinks right, provided he or she does not try to force others to live in the same fashion. Second, each individual has the right to acquire and keep property. If government is necessary, it is only to uphold these fundamental rights. Libertarians have generally been defenders of the market order, though their philosophical arguments have varied. Among their most important representatives have been Robert Nozick, Ayn Rand, Murray Rothbard, and F.A. Hayek. There is also a variant identified as left-wing libertarianism, found notably in the writings of Hillel Steiner.

Predominantly an American political movement of the twentieth century, libertarianism is a political doctrine whose deepest commitment is to liberty. Libertarians believe that the freedom of the individual is the most important value that should guide political reflection and that the good society is one in which that freedom is respected. Yet libertarians disagree about what a commitment to individual liberty entails politically and about the basis of this commitment. To understand libertarianism, then, it is necessary to come to terms with the variety within its tradition and with its relationship with other political ideas.

Libertarians approach liberty by asking what the legitimate functions of the state are. Broadly, they offer two kinds of answers. The libertarian anarchist answer is that no state is legitimate; for minimal state libertarians, however, the state is legitimate to the extent that its activities are confined to a limited range of functions, including national defense, the protection of individual rights, and the enforcement of contracts. Even within these alternatives, however, further divisions are to be found. Libertarians differ over the proper scope of government but also over the foundations of individual freedom. Any consideration of libertarianism, then, would have to account not only for the fundamental principles or commitments which give it shape and for the differences between minimalist and anarchist libertarianisms, but also for the varying doctrines advanced by libertarians from Robert Nozick to Murray Rothbard.

Fundamentals of Libertarianism

Origins

Libertarianism is a species of liberalism. Liberalism is a tradition of political thought which understands the good society as one in which individuals are free to pursue their own ends rather than one which enforces one particular understanding of what constitutes the good life. Central to liberalism is a commitment to individual liberty. For the liberal, liberty is a good which ought to be honored and protected; and doing so requires recognizing that each and every individual is entitled to a domain within which he or she may act without interference from others. Liberalism, however, describes a broad tradition which includes thinkers as diverse as John Locke in the seventeenth century and John Rawls in the twentieth century.

Libertarianism is that side of liberalism which emphasizes the importance of individual freedom from the state and which is generally wary of the operation of government. It is skeptical about power but especially about governmental power. Modern libertarians see themselves in this regard as the heirs of a long tradition in European thought, which champions the rights of the individual against the state. While they insist that this tradition stretches back into medieval times (when kings could not create law or legislate but only find or declare law,) it is to writers of the seventeenth century that they most commonly turn when looking for the first expressions of libertarian thinking. In particular, it is the ideas of the Levellers – John Lilburne, William Walwyn, and Richard Overton – and later of John Locke, which provide the inspiration for much of libertarianism.

Libertarians take two fundamental ideas from these thinkers. The first is that each individual is entitled to live as he or she chooses, provided he or she does not try to force others to live as he or she thinks right. The second is that each individual is entitled to acquire and keep property. If government is necessary, it is to protect these rights by securing individuals against those who would invade or aggress against their property and their persons. But any government that itself violates these rights by coercing them or taking their property without their consent, is tyrannical and may rightly be resisted.

Libertarianism has its origins in these ideas and its heroes are thinkers who have, in different ways, asserted the rights and liberty of the individual against the state. However, libertarianism as an intellectual and political movement did not emerge until after World War I in the United States. It arose largely as a response by some intellectuals to the growth of government and the rise of socialism. The most important writers who criticized socialism, central planning, and the growth of government were the Austrian economists Ludwig von Mises and F.A. Hayek who, throughout the 1930s and the 1940s,

debated the advocates of central planning over the feasibility of socialism. Although based in Europe, their work received a more enthusiastic reception in the United States among intellectuals hostile to the politics and economics of the New Deal. These included H.L. Mencken, Albert Jay Nock, Garet Garret, Rose Wilder Lane, Isabel Paterson, and Henry Hazlitt – journalists, writers, and economists who wrote warning of the dangers to constitutionalism posed by the growth of the state, touting the merits of free-market economics, and defending the virtues of American individualism.

It was in the 1950s that the term 'libertarianism' first came into use to describe this political stance, when Leonard Read, who established the Foundation for Economic Education, began calling himself a libertarian. While the term was rejected by writers like Ayn Rand and her followers, it came into use in the 1960s; and in 1971 the Libertarian Party was founded.

Principles

Libertarians share two sets of convictions. First, all individuals are entitled to live as they choose, free from interference by other persons or by the state. Second, in the absence of deliberate design by government or the state, order will prevail: granted the freedom to contract and exchange, markets will coordinate the production and distribution of goods better than any other available institutional mechanism. Yet, while most libertarians see these two convictions as consistent and mutually supportive, they differ over which is the fundamental basis of libertarian thinking. For Mises the commitment to individual freedom rests on straightforwardly utilitarian considerations: capitalism produces greater human welfare than socialism or the mixed economy. Yet for Murray Rothbard, the rights of the individual are defensible independently from any consequentialist argument.

Both of these convictions are intimately associated with libertarian thinking; however, it is the first which is more important philosophically, since it better identifies what is theoretically distinctive about libertarianism. For libertarians are particularly concerned to defend the freedom of individuals to live without being subject to aggression by others – against their persons or the property they may rightly acquire. An early statement of the first aspect of this claim was offered by the Leveller Richard Overton, in *An Arrow Against All Tyrants*: "To every individual in nature is given an individual property by nature, not to be invaded or usurped by any: for everyone as he is himself, so he hath a self-propriety, else could he not be himself, and on this no second may presume to deprive any of, without manifest violation and affront to the very principles of nature …" (Overton, 1646: p. 68). This is the thesis of self-ownership. And for libertarians, out of this thesis comes the contention that individual freedom includes the freedom to own private property. The most famous formulation of this claim is John Locke's in his *Second Treatise of Government*: "Though the earth, and all inferior creatures be common to all men, yet every man has a property in his own person. This nobody has any right to but himself. The labor of his body, and the work of his hands, we may say, are properly his. Whatsoever then he removes out of the state that nature hath provided, and left it in, he hath mixed his labor with, and joined to it something that is his own, and thereby makes it his property."

The centrality to libertarianism of self-ownership and the corollary right to own property, has led many to conclude that, perversely, the fundamental value for libertarians is not 'liberty' but the right to private property (including, but by no means only, one's property in one's person). All individuals must enjoy liberty; but only that liberty that is consistent with a respect for the property rights of others.

This understanding of individual rights is the basis of the libertarian view of the justification and proper role of the state. If individuals own themselves and have a right not to be aggressed against, no government is legitimate save that which enjoys the consent of the people. And the purpose of government is nothing more or less than protecting individuals against those who would violate their rights by invading their persons or their property. Libertarianism, in this regard, is profoundly antipaternalistic. It is no part of the purpose of government to improve people or society or even to provide for their welfare. It should not busy itself with human needs or deserts. Its only concern is individual rights.

The Market

Although its philosophical principles are what make libertarianism distinctive, the emphasis its adherents place on free markets and the virtues of market society is no less important. Libertarians defend capitalism and the market order. For many libertarians, capitalism is simply that form of economic organization which grows out of the freedom of individuals to exchange private property. For others, market society should be defended because it has important virtues of its own.

For thinkers like Hayek and Mises, the defense of the market was crucial to the defense of freedom because they saw the challenge to freedom as coming from modern socialism. Socialism, seemingly being put into practice in the former Soviet Union and gaining intellectual adherents in the West, criticized the market for being, at once, insensitive to the poor, who fared badly under capitalism, and less efficient than a properly planned economy. Markets were wasteful in production and inequitable in distribution. Socialism's attack on the market made the defense of the market necessary.

In the 1930s, Hayek and Mises devoted their energies to showing the impossibility of socialism understood as a form of economic organization which eschewed markets. In the absence of the signals sent out by market prices, economic coordination could not happen and central planners could not acquire the knowledge needed to effect such a coordination; for that knowledge was dispersed throughout society and often available temporarily and locally. Coordination without markets would produce shortages of some goods and an excess of others: supply and demand would never be in step. Hayek further argued that the deeper danger of socialist central planning was not economic but political. In order to pursue the goal of production without markets, planners would have to resort increasingly to coercion to curb people's natural proclivities to trade. Central planning required the creation of monopolies; and this would require suppressing those whose activities, intentionally or not, competed with monopoly suppliers. In the long run, Hayek argued, this posed a threat to political freedom, for it would undermine the rule of law by granting to some, privileges under the law.

This argument resonated particularly with libertarians in the USA in the 1950s. Here it was deployed less against socialism than against the expanding regulatory state. Government intervention in economic life, libertarians claimed, was neither necessary nor benign. More often than not, it upheld privileges – notably those enjoyed by producers and professionals seeking protection from competition which might challenge their monopolies. The most notable proponent of this argument in popular form was Milton Friedman, notably in his book, *Capitalism and Freedom* (Friedman, 1962). However, libertarians, unlike conservatives, also challenged the defensibility of government intervention, not only in the economy but also in other areas of society. Friedman and others took issue with the draft, the legal prohibition of drug use, licensing, and various other forms of compulsion by the state.

Another important target of the libertarian challenge was the welfare state. The state was not needed to provide what markets clearly could: health care, disability and unemployment insurance, and pensions, among other things. Government, libertarians argued, would, like any monopoly supplier, provide such services at greater cost and lower quality than would be found under competitive conditions. In part they objected to the limiting of individual liberty: compulsory retirement insurance, for example, compelled people to invest old age savings with the state, which provided only one of a range of possible retirement contracts – and not a particularly favorable one at that. The reply that such institutions were needed to ensure that people were protected should they fail to make provision for themselves, was rejected as paternalistic.

Nonetheless, libertarians have always disagreed over whether or not it is part of government's role to provide a welfare safety net. Hayek maintained that government needed to supply some forms of welfare because markets and charity would not be able to meet the demand. Friedman argued for a negative income tax to ensure that no one dropped below some minimum threshold. Insofar as libertarians have accepted the need for a public policy response to such problems as welfare, however, they have sought to remove the discretionary power of governments, which they think more likely to be captured by particular interests than to become the guardian of the general good.

Varieties of Libertarianism

While libertarians share certain general commitments or attitudes, they often differ both in the specific content and in the justification of their philosophical positions. The post-World War II period has seen the development of numerous attempts to state the case for, and the basis of, libertarianism.

Nozick's Minimal State Libertarianism

The most important mainstream libertarian is Robert Nozick, whose 1974 book, *Anarchy, State and Utopia* (Nozick, 1974), has been widely discussed and criticized. Beginning with the presupposition that "Individuals have rights, and there are things no person or group may do to them (without violating their rights)"; and the conviction that "So strong and far-reaching are these rights that they raise the question of what, if anything, the state and its officials may do," Nozick set out to examine, from a libertarian point of view, three of the fundamental questions of political philosophy: Can the state be justified?; What principles of justice must govern such a state?; and What would a good society look like if it ran along such principles?

Nozick's first concern is the repudiation of anarchism. He is a minimal state libertarian and the task of the first part of his book is to show how such a state can, and must necessarily, arise out of a prepolitical state without violating individuals' rights. For Nozick, individuals have rights to their persons and their property; and these rights act as 'side-constraints' on the actions of others, forbidding such others to act in any way that violates rights – even if violating rights would improve the general welfare or, indeed, help reduce the number of rights violations. Rights are absolute; they are also fundamental: rights are good in themselves and are not derived from some other, more basic, good. For this reason, rights cannot be weighed in the balance with other, competing goods.

In these circumstances, how could a state ever be justified? Nozick tries to show that without rights being violated, a minimal state would emerge out of a state of nature in a four-stage process. First, individuals would form mutual protection associations in that condition, so a number of protection agencies would appear. Second, one agency or federation of agencies would come to dominate any given area – through its superior economic efficiency and without any violation of rights. Third, the dominant agency will rightly be entitled to protect its clients against independent agencies because individuals have the right to protect themselves. Finally, however, the dominant agency will have to extend its protection to those independents by way of compensation for the violation of their (and their clients') rights. Emerging out of all this is a minimal state – one which claims a monopoly on the use of force, while offering protection to all.

What remains doubtful in all this is whether such a state is indeed consistent with libertarian principles, since it must deny persons the right to enforce their rights against others and require them to pay taxes. And Nozick has duly been criticized for this, particularly by libertarian anarchists. No less controversial, however, is Nozick's insistence that only a minimal state is justifiable: it is no part of the state's right or duty to do more than offer protection. Nozick's theory of distributive justice explains why.

According to Nozick, justice is a matter of how people have come to have the goods they have rather than a matter of the pattern of distribution of people's holdings. Unlike the theory of John Rawls, Nozick's theory is historical rather than structural. There are three principles of justice in holdings: a principle of justice in the acquisition of property; a principle of justice in transfer; and a principle of justice in rectification of past injustice. According to this view, if property is justly acquired and justly transferred, the resulting distribution of property is, necessarily, just – however small or great the resulting differences of wealth or income among people.

What, however, would make an original appropriation of property just? Can the first person to come across unowned property simply acquire it all? In Nozick's theory, original acquisition is constrained by the 'Lockean proviso' that each is allowed to appropriate as much as he or she desires, provided

"enough and as good [is] left in common for others." The importance of this proviso lies not only in what it forbids by way of future appropriation, however, but also in its implications for all existing holdings. How a person may transfer property will also be governed by the Lockean proviso; and an earlier violation of the proviso may cast doubt on the worth of a particular property right.

Nozick's insistence on the importance of the proviso is consistent with his view of justice as historical rather than structural. His theory is as much an attack on patterned or end-state theories as a defense of his own 'entitlement' theory. End-state theories think of justice in terms of some particular distributive outcome, with which principles of distribution must conform. For Nozick, this is incompatible with a proper understanding of justice and of rights. But he has a further objection: the attempt to secure preferred distributive patterns necessarily requires interference with the voluntary activities of individuals. Liberty upsets patterns, so liberty will have to be compromised if patterns are to be preserved.

Nozick's theory of justice has been vigorously criticized, however, by those who reject his libertarian starting point as well as by others who want to resist his conclusions. The thesis of self-ownership and Nozick's account of its implications, have been subject to searching examination by G.A. Cohen, in particular.

Rand's Objectivism

While Nozick has dominated academic philosophy, however, no libertarian has reached a wider audience than the Russian-born American writer Ayn Rand. In a series of novels, most famously *The Fountainhead* and *Atlas Shrugged* (Rand, 1943, 1957), essays, and newsletter articles, she offered a vigorous defense of capitalism and articulated a comprehensive philosophy – 'Objectivism' – which claimed to set individual rights on a firm epistemological and metaphysical basis.

Capitalism, according to Rand, "is a social system based on the recognition of individual rights, including property rights, in which all property is privately owned." On this account, capitalism is understood, or at least defined, not as an economic system but as a social arrangement consistent with the principles of ethics. Capitalist society is one which respects individual rights. The question, however, is: What rights do individuals have? and Why do they have these (and not any other) rights? Rand defines the rights an individual has by saying that "for every individual, a right is the moral sanction of a *positive* – of his freedom to act on his own judgment, for his own goals, by his own *voluntary*, uncoerced choice. As to his neighbors, his rights impose no obligations on them except of a *negative* kind: to abstain from violating his rights." Rights are thus freedoms to act but not assurances of anything more than forbearance on the part of others. An important corollary of this, however, according to Rand, is that the individual has a right to acquire property, since human beings need property if they are to survive. The basis of individual rights, she argues, is the right to life. "The right to life is the source of all rights – and the right to property is their only implementation. Without property rights, no other rights are possible. Since man has to sustain his life by his own effort, the man who has no right to the product of his effort has no means to sustain his life." But none of this means that an individual is entitled to any particular share of property. All it means is that no one may rightly be prevented from seeking to acquire property noncoercively and that no one should be prevented from using as he or she wishes, the property he or she has rightly acquired.

Rand, in her extensive writings, attempted to defend this stance by showing that it followed from a proper understanding of humans' nature and a grasp of the value of life. This philosophy is called 'objectivism.' Beginning with assumptions about the existence of an "objective reality," the centralilty of life as a value, and the importance of reason for human survival, she claims to have shown that the only ethically defensible social system is capitalism. Even within libertarianism, these arguments have proven controversial. Nozick, for example, finds them unconvincing. But there has been no shortage of philosophers, such as Douglas Den Uyl and Douglas Rasmussen, for whom the construction and defense of a Randian position continues to be an important task.

Although Rand, unlike Nozick, receives little attention from mainstream academic philosophers, the extent of her influence and the interest of her thought should not be underestimated. Not only do her books continue to reach a large popular audience, making her one of the best-selling authors of the twentieth century but she has also exerted a significant influence on academic philosophers, economists, and policy-makers (the most famous being Alan Greenspan, Chairman of the Federal Reserve Bank and co-contributor to Rand's *Capitalism: The Unknown Ideal* (Rand, 1967)).

Murray Rothbard's Libertarian Anarchism

For Ayn Rand, a proper understanding of human rights could yield only a conception of government whose role was limited to the protection of individual rights. Even then, taxation would have to be voluntary; for government, as policeman, could not violate individuals' rights by taking by force what individuals were not prepared to give up. For many libertarians, however, individual rights are in no way compatible with the existence of the state. The most important libertarian defender of the anarchist position was Murray Rothbard.

Rothbard has been libertarianism's great polymath: an economist in the Austrian tradition, he was also a historian and social philosopher, as well as a pamphleteer of the highest order. His works ranged from a treatise on economics, *Man, Economy and State*, to a history of *America's Great Depression*, to a philosophical examination of *The Ethics of Liberty* (Rothbard, 1970, 1972, 1982).

According to Rothbard, the 'crucial axiom' of the libertarian creed is this: "no man or group of men have the right to aggress against the person or property of anyone else." Aggression is defined as "the initiation of the use or threat of physical violence against the person or property of someone else." Central to libertarianism, then, is "the absolute right to private property of every man: first, in his own body, and second, in the previously unused natural resources which he first transforms by his labor." In Rothbard's view, these two axioms, "the right of self-ownership and the right to 'homestead,' establishes the complete set of principles of the libertarian system."

In common with Nozick and Rand, Rothbard holds that individuals have rights to do as they wish, so long as they do not invade the rights of others. Thus, individuals should be free to use or dispose of their property as they see fit and live their lives – as well or as badly – as they wish, provided they do not violate anyone's rights. However, Rothbard also maintains that the existence of the state is incompatible with libertarianism, for the state, by definition, must infringe these basic rights. Nozick's 'immaculate conception' of the state, he argues, is unsuccessful both because the logic of its derivation is flawed and because, even if it could be shown that a state could arise without the violation of rights, this would not serve to legitimize that state (nor, *a fortiori*, any existing state). Nozick, however, has at least offered a philosophical argument attempting to rebut anarchism. Rand, on the other hand, according to Rothbard, does little more than evade the difficulty posed by her own libertarian principles, for her claim that there is a role for government and for her allegiance to the American state. Rand's patriotic defense of America during the Vietnam War was untenable for Rothbard, given the fact that military conscription – is an unambiguous violation of the libertarian principle of nonaggression and its prohibition of involuntary servitude.

For Rothbard, minimal state libertarianism must either abandon libertarianism's core commitment to nonaggression or lapse into incoherence. None of the extant nonanarchist forms of libertarianism have come to terms with this problem, since none have been able to explain how the most fundamental need of the state – to raise revenue by taxation – could be accounted defensible in libertarian terms. More than any other libertarian, Rothbard has tried to push the principles of libertarianism to their logical conclusion; to show that if individuals have rights, no form of authority which might invade their persons or take their property without their consent, is morally legitimate.

Hillel Steiner's Left-Wing Libertarianism

In rejecting as flawed the libertarianisms of Nozick and Rand, Rothbard assumes that individuals not only have property in their persons but also can acquire just title to property in the external world. Indeed, for Rothbard, the right to acquire property is not constrained by anything like a Lockean proviso that enough and as good be left over for others. Should all land, for example, be appropriated by those who come to it first, leaving nothing for the johnny-come-latelies, that is, simply, the way of the world. Thus he rejects the idea, associated in the nineteenth century with Henry George, that the earth itself cannot be owned, even if individuals can own the product of their labor. If the original land is nature- or God-given, he argues, then so are all the people's talents, health, and beauty; if land must be owned only by society, so must everything else. Rothbard therefore rejects any idea that we start by assuming that everyone has an equal claim to land or to the earth or its resources.

Yet this is itself a highly controversial issue. And some libertarians, notably Hillel Steiner in his *An Essay on Rights* (Steiner, 1994), have argued that the correct starting point is an assumption of an equal right of all to the earth and its resources. Persons have, on this account, two original rights: to self-ownership and to an equal share of initially unowned things. Each 'person' is entitled to ownership of himself, for to be owned by others is to be a slave; and so only 'things' may be owned by others. But no one is entitled to appropriate every unowned thing. Indeed, no one is entitled to appropriate more than the Lockean proviso allows. In a world of fully appropriated things, "each person's original right to an equal portion of initially unowned things amounts to a right to an equal share of their total *value*." Moreover, and correlatively, any person's possession of a just title to any thing, encumbers him or her with a duty to pay every person an equal share of its value. Since there is, Steiner argues, no moral right of inheritance, – for only existing (and not past or future persons) have rights – the upshot of all this is that a just distribution of things must reflect our original rights, and not the accidents of history or geography. Our just entitlements do not depend upon where, or to whom, we were born. The implication of this libertarian view is that the recognition of libertarian rights is fully consistent with, and indeed requires, a significant measure of property redistribution among persons, and that means all persons, regardless of nationality.

From such libertarian premises, some, like Philippe Van Parijs, who would not describe themselves as libertarians ideologically, go on to argue that justice requires recognizing that everyone is entitled to a form of unconditional basic income. As he points out in *Real Freedom for All*, the core problem for libertarians is to find a nonarbitrary criterion of original appropriation. Homesteading or an application of the principle of 'first come, first served,' is not, in this view morally defensible; for it would be a serious error to suggest that anyone could be free living under a regime in which he or she has no property rights, except in his or her person, since all property has already been appropriated and bequeathed. This left-wing libertarianism takes much more seriously the importance of equality as a moral consideration, just as the other variants of libertarianism reject its significance altogether as a substantive value.

Libertarianism as Ideology

Politically, libertarianism is often identified as a 'right-wing' ideology but, in fact, its position on the ideological spectrum is problematic. While some libertarians, like Rand, describe themselves as opponents of 'the left' or as right-wing, others, like Rothbard, see themselves as having much more in common with the left as opponents of the state – which they tend to see as the captive or instrument of big business. Moreover, most libertarians try to distinguish (if not dissociate) themselves from conservatives, since they reject the conservative's interest in the regulation of personal morality. To the extent that they align themselves with any other ideological viewpoint, libertarians are inclined to describe themselves as the heirs of classical liberalism. Libertarians as diverse as Hayek, Rothbard, and Steiner have been ready to describe themselves as classical liberals.

In public affairs, however, libertarianism has found itself allied, more often than not, with the conservative side of politics. Over the short history of modern libertarianism, some

conservatives have tried to transform it by incorporating its commitment to liberty but rejecting its hostility to authority and tradition. A notable advocate of such a 'fusionist' view was the American conservative Frank Meyer. To date, however, libertarianism has resisted such attempts. It remains a more radical political philosophy than conservatism can countenance.

Editor's Note

Popular and scholarly attention to libertarian political philosophies in the United States has increased since the original publication of this article, largely because of the Presidential candidacies of Ron Paul and his son Rand Paul. Recent works that will be of interest to readers include: David Boaz, 1997; Peter Vallentyne, 2012; Manuel Vargas, 2014; Serena Olsaretti, 2013; Eric Schansberg, 2002; Alfred R. Mele, 2013.

Abstract

There are many types of libraries, each with their purpose within the communities they serve. While differences define each type of library, commonalities exist among all. The various types of libraries are briefly described and then in greater detail defined in terms of their relationships with finances, information, individuals, communities, and place.

Introduction

Since their beginning, libraries have collected, organized, archived, and made accessible the intellectual output of humankind. Dating back to 2600 BCE in Sumer, the earliest known libraries were found to have clay tablets with cuneiform script documenting commercial inventory and transactions. Today's libraries contain a diversity of formats covering a wealth of subject areas. There are many types of libraries, each with their purpose within the communities they serve. While differences define each type of library, commonalities exist among all. The various types of libraries are briefly described and then in greater detail defined in terms of their relationships with finances, information, individuals, communities, and place.

Types of Libraries

Libraries are defined foremost in terms of the community served and also with regards to their physical structures, types of information stored or accessed, and funding sources.

Academic, university, or college libraries are designed to support the teaching and research needs of the faculty, staff, and students affiliated with academic institutions. Most research libraries are supported by universities, although some are public or governmental institutions. Research libraries are designed to be comprehensive and exhaustive in their coverage of subjects and acquisitions are permanent. Physical libraries are designed with particular subsets of a university's population in mind, such as undergraduate, law, medicine, and science. In the last 20 years, new acquisitions have trended toward a digital format, especially in the case of journals and more recently, books. As more and more university libraries move content online, the physical space of the library is being allocated for communal purposes, such as social and meeting spaces and computer workstations (Dewey, 2008). Public university libraries are largely funded through tax funds and student tuition. Private universities are supported by tuition and endowments. Academic libraries have faced budget difficulties owing to the rising cost of journal subscriptions and as a result many have saved money through collaboration and participation in open access publication initiatives (Bosch et al., 2011).

Corporate or special libraries are found in a variety of business settings: law firms, hospitals, news publications and broadcast companies, and pharmaceutical companies. These types of libraries serve specialized clientele and as a result have collections that have great depth but little breadth. Currently, for most special libraries, materials are acquired electronically. The library is considered a support service and as a result the physical space is small; often it is an office within a larger physical plant of the corporation. Librarians working in corporate environments often possess knowledge specific to the domain and work alongside other members of the organization. Often librarians will manage the company's intellectual capital and as a result fill knowledge management roles as well; principally, codifying knowledge to develop information retrieval systems and taxonomies specific to the corporate enterprise. Corporate libraries are supported by company profits and when companies experience loss, the library budget is likely to be one of the first cut as it is considered a support service (Corcoran, 2002). That having been said, studies from Kuwait, New Zealand, South Africa, and the United States indicate that jobs in corporate libraries and in knowledge management initiatives continue to grow.

Various levels and agencies of government have libraries. Many countries have national libraries, such as Nigeria, South Africa, Portugal, France, Germany, Scotland, Great Britain, China, and India, with the United States being an exception. National libraries serve the function of a depository of the national publications (both print and electronic), provision of reference, bibliography, preservation, and lending services; preservation and promotion of the national cultural heritage; and leadership in literacy campaigns (IFLA, 2010). Government agencies will support libraries to manage information produced by that agency as well as the information needed to support the research and information needs of the agency. For example, the National Aeronautics and Space Administration (NASA) and the European Space Agency (ESA) have libraries that support science and engineering research. Government information is moving online as well as government libraries. The Government Printing Office in the United States distributes more than 95% of its information in a digital format (Chadwick et al., 2012). Government libraries are funded by taxes and therefore must provide access to citizens as well as agency members. Their dependence on taxes for funding also means that their vitality waxes and wanes with the economy. For example, in the United States, the Environmental Protection Agency (EPA) closed all of their physical library locations in 2006 and moved access to EPA resources online in a money-saving effort. However, the outcry from their community of

users was so great that the physical libraries reopened within 2 years.

Public libraries are open to all members of a community. By design they are intended to serve the educational and entertainment needs of community members from cradle to grave. As a result, materials available through public libraries range from picture books to scholarly journals. The most heavily used public library collections today are comprised of children's materials and popular reading for adults. Most public library acquisitions are still in print format, but in recent years many public libraries have seen an increase in digital acquisitions, particularly electronic books. In many communities, public libraries are the only free source of access to the Internet and are instrumental in addressing problems associated with the digital divide (Jaeger et al., 2012). A public library is typically a system of one large central library and several smaller branch libraries serving neighborhoods within the system's service area. In general, libraries are funded in varying degrees by public and private sector funds. Public libraries are typically funded by tax dollars, although in certain countries small membership fees are also charged, such as the Netherlands, Alberta (Canada), Zimbabwe, and France. Funding for public libraries has been increasingly threatened in recent decades. The global economic crisis of 2007–11 brought closure to many public library branches (American Library Association, 2012). However, in many instances, public protest and willingness to fund local libraries through special tax initiatives kept doors from closing.

School libraries support the information needs of students and faculty of primary and secondary schools. A school library is typically one room within the school's facility. Materials are both print and digital with some schools opting for an all-digital environment. School libraries were early adopters of multimedia materials and as a result were initially called media centers. School libraries support the classroom curriculum and the leisure reading of students. As educators, school librarians collaborate with classroom teachers to support reading and development of information literacy skills of students. Funding for public school libraries is most often taxed based, and like public libraries, school libraries have experienced a reduction in services and resources provided in recent years, including the services of professional librarians. Studies have shown that students who have access to school librarians outperform those that do not on tests related to reading development.

Digital Libraries

The influence of digital information has changed the perception of libraries and libraries themselves. Many myths surround technology and information; for example, it is commonly thought that individuals no longer need to consult information intermediaries, travel to a library, or seek a publisher's permission to publish (Brown and Duguid, 2002). As the lines between authors, publishers, and distributors of information blur, there has been much speculation about libraries going the way of the travel agency and the newspaper. In many cases, technology has fundamentally changed the ways in which information is accessed and published; however, there are still for-profit industries thriving on the fact that not all digital information is free. Digital libraries are conduits to accessing both proprietary and freely available digital information.

A digital library has been defined in a diversity of ways depending on the perspective, user or designer. Digital libraries are purposefully constructed of electronic records which are collected and organized to meet the information needs of a specific community of users. Further, these libraries have technical and functional capabilities that support searching for, using, and creating information (Borgman, 1999). Digital libraries are international in scope and are usually created and maintained by university libraries and academic departments, public libraries, or government agencies (Witten, 2003).

Digital collections are often the electronic resources and services that exist alongside a physical library. Library users can use digital libraries and collections from their homes and offices. Technology allows library services and resources to be delivered seamlessly to individuals allowing for personalization of use within the user's own information environment. The distance between the individual and the physical library has been removed and access to information has been decentralized. The virtual or digital library becomes one information resource among many, whereas the physical library remains a beacon of knowledge within its community.

Finances

On the whole, libraries are nonprofit organizations and do not produce an information product but provide services that support access to information. However, libraries are in the position of doing business with organizations that are for-profit. Publishers, journal aggregators, book distributors, and authors need to turn profits in order to survive. The growth of the information economy and the influences of technology on information access have made the economic challenges faced by libraries even more acute. In the cycle of publication, libraries have traditionally filled the role of providing long-term access by preserving published works and making them intellectually accessible through organizational systems. The current system for funding libraries speaks to the good that society believes libraries possess and to the fact that individuals cannot produce the same level of organization and access to these materials less expensively on their own. Hence, the need for formal organization of information has economic justification. Information may be readily accessible and affordable to the individual but it is the long-term access and organization of that information that individuals cannot afford.

The decentralization of information has led some to believe that libraries' role in information access will lessen as information intermediaries are no longer necessary. However, it is unlikely that publishers or individuals will want to or are in the position to take on the roles of preservation and long-term access. The recent struggle over access to electronic books between public libraries and book publishers indicates that publishers may feel that a new paradigm is upon us (Besen and Kirby, 2012). Libraries have the right to loan materials indefinitely given the first-sale doctrine. This level of accessibility to readers reduces the level of profit for publishers and authors. The laws that applied to physical print-based materials are no longer applicable to electronic information. Individual and

public rights and privileges associated with electronic information are still being worked out in the courts (Electronic Frontier Foundation, 2012).

Further, libraries more often than not pay for licenses to access digital information rather than own it outright. Licensing agreements can inhibit lending practices and long-term access. Through collaboration and advances in the technical infrastructures of libraries, librarians have been successful in negotiating perpetual access and unhindered lending privileges to digital information (Lipinski, 2012). The library as both a learning and memory organization will keep libraries from simply becoming an office that manages licenses and contracts. And as learning and memory are fundamental to human existence, libraries will always be a part of the human experience.

Information

Libraries are defined, in part, in relationship to information. Information has been defined in a variety of ways. Information as process is the act of being informed. Information as knowledge is that which reduces uncertainty. Information as thing refers to objects such as documents and data (Buckland, 1991). Documents are stored or made accessible by libraries for the purpose of facilitating the exchange of information as knowledge between the author and the reader.

Libraries have evolved from a primary relationship of owning and storing information to one that now includes providing access to documents without necessarily either owning or storing the documents. The degree to which ownership is privileged over access varies mostly depending on type of library and the extent to which technology drives document formats.

Selection, organization, and preservation are three major functions that define a library's relationship to information as thing, particularly information that is owned by the library.

Based on the professional values of librarians, libraries provide diverse viewpoints on any topic included in a library's collection. Objectivity and neutrality in the development of collections supports the notion that libraries are a place for all members of a particular community. As mentioned earlier, libraries make selections based on the information needs of their community members. Selections are prioritized for acquisition based on those needs and budgetary constraints. Judgments are made as libraries cannot afford to purchase or physically hold every book relevant to its community's needs.

Traditionally, libraries filled information requests not met by their collections through interlibrary loan. Interlibrary loan is supported by member libraries that are willing to lend books, journal articles, and other media to other libraries in the network, who then in turn lend those items to their users. The process has become less labor and time intensive given the influence of the Internet. Requests for journal articles are filled within minutes or hours, while physical books travel more slowly in real time; however, even this is changing. An example would be HathiTrust, a collaborative large-scale digitization project resulting in a shared repository with nearly 6 million books accessible online. Digitized and networked information have created a level of cooperative collection-building previously not thought possible.

Organizational systems, cataloging, classifying, and indexing provide long-term intellectual access to materials that are owned by libraries (Svenonius, 2000). Traditionally, these systems have taken considerable time and effort on the part of librarians to implement; each document needing to be examined, interpreted, and described for cataloging, classifying, and indexing. These three systems along with bibliography allow for comprehensive access to a library's collection and the contents of that collection (Mann, 1994). These organizational systems are necessary, for without the means to provide long-term intellectual access there is little need to provide for long-term physical or digital preservation.

Organizational systems are changing to take advantage of enhanced access capabilities possible in a networked information environment. Recent developments to cataloging and cataloging records include the use of entity relationships, metadata, and user-generated subject tags. All of these changes allow for greater interoperability of cataloging records, liberating them from the confines of a single collection or institution (Gardner, 2012). The shift in importance to access of digital information is transforming organizational systems which traditionally provided static, structured, and pre-coordinated access to documents into a system that includes dynamic search processes. Keyword searching has become the norm foremost while the use of controlled vocabularies, like the Library of Congress Subject Headings, is left to the domain of information professions. The ephemeral nature of keyword searching is a conceptual match for the immediacy that networked access to digital information provides. However, for long-term access, formal systems of bibliographic control are essential.

As mentioned earlier, long-term intellectual access is the first step toward preservation. There is an understanding that libraries, like museums and archives, are memory organizations created in part to preserve the documentation that represents our collective past. There is the expectation of preservation of physical and digital information alike. The science of preserving physical materials is well established with film and sound recordings presenting the greatest challenges in analog preservation (Ross, 1993). Digital preservation is an evolving science with emphasis on collaboration, open source formats, technical metadata, redundant systems, and migration strategies (Caplan, 2008).

Libraries face additional challenges to preservation of digital information, especially that which is accessed rather than owned. This type of arrangement provides for use but not necessarily for long-term access. In addition to licensing access to content, libraries are also licensing the search interface, delivery platform, and the hosting space on a server. Libraries can negotiate perpetual access to digital information but a technical infrastructure of support must also exist in order to ingest that content into their collections. Smaller libraries with limited resources and staff expertise are likely not able to ingest large quantities of digital content.

Collaboration among libraries and other agencies concerned with long-term access to the cultural record is necessary for digital preservation. The Lots of Copies Keep Stuff Safe

(LOCKSS) Program and HathiTrust are examples of two successful collaborations. LOCKSS is designed to provide libraries and publishers with perpetual access to electronic subscriptions to journals and books. Supported by numerous universities, Google, the Internet Archive, and Microsoft, HathiTrust is a digital preservation repository comprised of works in the public domain as well as copyrighted works. While beneficial to researchers, the inclusion of copyrighted works resulted in legal challenges to HathiTrust. These collaborative efforts indicate the continued importance of libraries to provide information through ownership. The desire for long-term, equitable access to the cultural record will be realized through a preservation plan that is based on the cooperation of networks, libraries, publishers, and document creators. As a result, libraries will become increasingly social entities – entities that are as much defined by their communities of users as by their communities of collaborators.

Individuals

Libraries are also defined by their relationships with individuals. Libraries are sources of connection, education, entertainment, and inspiration for individuals. Libraries have moved from a static one-way relationship between document and user to a system of information processes that facilitate knowledge building. Libraries provide the opportunity for the transfer and exchange of information as process and as knowledge. Through libraries, individuals connect with librarians and other users and with ideas expressed in documents. Individuals can engage with processes that facilitate interacting and innovating through these connections.

Libraries educate individuals through access to librarians and documents. Libraries have always supported individual learning both formal and informal. The public library is often referred to as the university of the people as it offers endless resources for lifelong learning. Librarians assist individuals with information seeking and help them find the resources they need. These interactions occur in the library and online using e-mail or chat services and with varying intensity and duration depending on the nature of the information need. Increasingly, individuals turn to libraries and librarians to learn how to navigate the vast and rapidly growing information landscape in which libraries are only one resource for information among many. This is seen in an increase in information literacy skills instruction in all types of libraries (Breivik et al., 1998). Through this type of instruction, librarians help individuals develop the skills necessary to find, evaluate, and use information effectively.

Libraries have a special relationship with a particular sort of individual: authors. Libraries provide the resources to generate the creation of new knowledge and new works. Unlike other agencies involved with the production of published works, libraries are committed to providing long-term access to those works. In this way, they play a role in the life cycle of knowledge and the creation of new works. Authors look to the memories and cultural context preserved and organized by libraries to generate new ideas. Sir Isaac Newton once said that new insight is obtained by standing on the shoulders of giants; those giants are the authors whose works live on in libraries.

Community

The relationship between a library, regardless of type, and its community of users is paramount to understanding the nature of any particular library. The information needs of a library's community of users determine the resources and services offered by that library. The relationship between library and community is reciprocal. The library influences the lives of its community members. Until recently, historians mostly examined the influence of libraries on the individual, community, and society rather than the influences of individual readers on the development of the library (Wiegand, 2011). Libraries are now often assessed in terms of how well they are meeting their communities' needs through the evaluation of community demographics, usage statistics, and surveying users for feedback on satisfaction related to resources and services (Westbrook, 2001).

Libraries facilitate connections within communities among community members and organizations. These connections are believed to contribute to the development of social capital within a community. Social capital describes the networks and connections among individuals within a community that foster social trust and cooperation for the benefit of all (Putnam, 2000). Neighborhoods with a high level of social capital are more likely to have heavily utilized libraries; both entities thrive together.

Within a community, libraries can be an information node among many, such as bookstores, museums, archives, government agencies, and retail stores. Libraries are also considered a channel for information along with the Internet, family members, and experts. In their capacities as nodes and channels, they serve as distribution points for information. Access to government information provides a clear example of this, particularly in times of crisis. In recent history, following natural disasters in Chile, Haiti, Japan, New Zealand, and the United States, public libraries were significant in the recovery processes in the areas affected. Individuals sought out libraries to connect online with family members and to gain access to government information and other resources to aid in their personal recovery.

As mentioned previously, governments are moving much of their information to an online-only format. Access to this information is essential for government to function, yet government cannot require or expect individuals to afford the technology needed to access digital information. With the move to online distribution venues, public libraries and librarians have become indispensable as information intermediaries for a variety of government agencies. In many communities, the public library is the only source of free access to online information. While access to government information has been decentralized through the use of the Internet, which ultimately increases access, physical access to a device is still required. Digital information requires an infrastructure of support; the information must be rendered before it can be utilized. The necessary devices and networks must be located in close proximity to the citizenry. Public libraries provide a ready solution to this problem. Also, librarians are available to help individuals navigate the technical and intellectual aspects of finding and using government information.

Communities are documented and represented through library collections. In the largest sense, libraries document communities of scholars and authors. Libraries of all types represent their communities through the documentation and preservation of intellectual and cultural output. In academic libraries, institutional repositories are being built to collect and preserve the digital works of faculty and students (Lynch, 2003). Likewise, corporate and government libraries are building repositories to preserve and to provide access to the intellectual output of their constituents. These efforts benefit the institutions as a whole as these collections encourage collaboration among researchers and make accessible information for reuse. While public libraries are creating digital collections of unique materials, they have been less inclined to build community repositories to collect the intellectual and creative output of its community members. However, public libraries have the potential to play a significant role in documenting and preserving the social history of their communities (Copeland and Barreau, 2011).

Place

Libraries as place are often central to community life. In the words of historian Shelby Foote, "A university is just a group of buildings gathered around a library." Libraries are the intellectual and social centers of academic life. Community spaces and technologies that facilitate group work have been added to the physical structures of academic libraries. Public libraries have been referred to as third places, with first and second place being home and work, respectively. A third place is a neutral place where individuals from all backgrounds from a community meet to converse with neighbors in friendly manner – a place to be connected to others around ideas not related to work or family (Oldenburg, 1999). Libraries provide community members with a neutral yet vital environment to engage in a host of human activities.

Libraries are monuments. Many large cities around the world have libraries that are architectural feats and deserve admiration for their design alone, regardless of the collections contained within. Sendai Mediatheque, Japan; National Library, France; Villanueva Public Library, Colombia; and José Vasconcelos Library, Mexico, are all examples of buildings notable for their aesthetics. The grandeur of these libraries reflects their value to society and the value of what is contained therein. The buildings are as symbolic as they are functioning agencies of information. Libraries have their place among the cultural landscape along with museums, cathedrals, and theaters. The *Book of Kells*, an illustrated manuscript of the Gospels authored by Celtic Monks circa 800 CE, on permanent display at the Trinity College Library in Dublin, is often referred to as Ireland's finest national treasure. This one book attracts over a half million visitors each year. Libraries document the accomplishments of humankind, and by doing so celebrate us all.

As of 2002, approximately 92% of all new information created each year is stored on magnetic media (Lyman, 2003). The predominance of digital information has significant and long-lasting implications for libraries' collections and physical spaces. The digital information age has just begun and the long-term implications of this major shift in communication are yet to be fully understood. While organizing and preserving digital information for access and use is a cultural imperative, the need for libraries to maintain physical collections is just as important. Collectively, libraries have spent countless sums of money on physical materials documenting hundreds of years of human accomplishments. These materials are valuable as information and as artifact. In many instances, through digitization, libraries are creating digital collections of unique materials from their collections. Libraries are making content accessible that would otherwise not be available without physical use of a library. In this way, online access extends the presence of the physical library and integrates its resources with the greater web of knowledge.

Life Course and Event History Analysis

Hans-Peter Blossfeld, European University Institute, Fiesole (FI), Italy
Gwendolin J Blossfeld, Nuffield College, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Life course analysis has become a very active research field. This article summarizes the main research questions of the life course paradigm and its most important theoretical concepts. It also reports some recent research findings of life course studies. Then, this article introduces the terminology and models of discrete and continuous event history analysis. A concrete event history analysis example is given in order to demonstrate the strength of life course studies.

Introduction

Life course analysis has become a very active research field in the social sciences these last decades for good reasons. Large retrospective life history and prospective panel data sets are now available in most modern societies. Well-known examples are the National Longitudinal Surveys (NLS66, NLS79, NLS97, NLSW) or the Panel Study of Income Dynamics (PSID) in the United States, the Life History Study, the Socio-Economic Panel Study (SOEP), or the National Educational Panel Study (NEPS) in Germany, the National Cohort Studies (NSHD, NCDS, BCS70, MCS), the British Household Panel Study (BHPS), and its successor, the study Understanding Society, in the United Kingdom, or the Household, Income and Labour Dynamics in Australia (HILDA) Survey. Most of these data sets are nationally representative for the population or some selected birth cohorts. They provide longitudinal data on intergenerational relationships, educational histories, job trajectories, family careers, fertility events, changes in health status in the life course, and often also data on the life courses of other family and household members such as partners or spouses. Life course data explicitly recognize the dynamic nature of social roles and circumstances as men and women move through their life paths, the interdependence of lives and life choices, the situational imperatives confronting actors in various phases of the life course, and the accumulation of advantages and disadvantages experienced by the individual over the life course (Elder et al., 2003; Crosnoe and Elder, this volume). The dynamic analysis of life course data is a rewarding but formidable challenge. It has been made possible by the development of statistical methods such as event history and panel analysis. These methods do not only allow studying changes over time but also offer better opportunities for a more appropriate time-related causal analysis (Blossfeld et al., 2007).

This article focuses on the close interrelationship of life course and event history analysis. Event history analysis is the statistical study of processes that are characterized in the following general way: (1) there is a population of individuals, each moving among a finite (usually small) number of life course states; (2) these changes (or events) may occur at any point in time; and (3) there are time-constant and/or time-varying factors influencing the timing of these events. Examples are workers who move between unemployment and employment; men and women who enter into consensual unions or marriages; people who are mobile between different regions or nation-states, and so on. This article first summarizes the main research questions of the life course paradigm and its most important theoretical concepts. It will also report some recent research findings of life course studies. Then, this article introduces the terminology and models of discrete and continuous event history analysis. Finally, a concrete event history analysis example is given in order to demonstrate the strength of life course studies.

Life Course Analysis

In the last four decades, there have been great advances in the study of lives over time, and they extend across various disciplines such as sociology, developmental psychology, demography, or medical sciences (Carr, 2008). We limit ourselves to the literature in the social sciences (Elder and Giele, 2009). Here we identify at least five typical research questions of life course researchers.

Studying the Endogenous Logic of Trajectories in the Life Course

A first aim of life course researchers is to study the endogenous (causal) logic of trajectories over the life course. In sociology, the concept of trajectory is often used to refer to an individual's sequence of roles in one domain of life such as the education, work, or family career. The conceptual tool of trajectory encompasses both sequences of different qualitative states (e.g., being single, married, or divorced in a family career) and continuous increases or decreases in quantitative characteristics (e.g., such as income or competence trajectories). In this article, we limit our discussion to life course studies that record and analyze the sequence of qualitative states occupied by individuals over the life course and the timing of changes among these states. For example, an event history of job mobility consists of more or less detailed information about each of the jobs and the exact beginning and ending dates of each job.

Data on trajectories are often collected retrospectively in so-called life history studies. Collecting retrospective data is cheaper than panel studies and has the advantage that they code the life course data into one framework of codes and meaning. But retrospective studies also suffer from several

limitations (see Blossfeld et al., 2007). In particular, data concerning motivational, attitudinal, cognitive, or affective states are difficult (or even impossible) to collect retrospectively because the respondents can hardly recall the timing of changes in these states accurately. Also the retrospective collection of behavioral data has a high potential for bias because of its reliance on autobiographic memory. To reduce these kind of methodological problems, modern panel studies (e.g., the PSID in the United States, the BHPS and the Understanding Society study in the United Kingdom, or the SOEP and the NEPS in Germany) are using a mixed data collection design which combines traditional panel information (i.e., multiple observations on the same individuals at discrete panel waves) with retrospectively collected event history data for the period before the first panel wave and between the successive panel waves. This combined design also allows linking information about an individual's prospective life planning (e.g., career or family planning) collected in earlier panel waves, with life course behavior recorded in later panel waves.

Trajectories of individuals often depend strongly on the structural context and thus draw theoretical attention to societal traditions and norms, social institutions, and organizational structures shaping the careers of individuals. For example, institutions such as the educational system define the times of possible school transitions in the life course and structure the school options available to individuals at certain points in their careers. For example, Shavit and Blossfeld (1993) have found declining effects of family background on successive educational transitions over the educational career for a broad selection of modern societies. It is, however, still an open question, whether the empirical pattern of declining social background effects across successive educational school transitions is (1) a life course effect because the students get increasingly independent from their families of origin, or (2) a selection effect since at each transition only the most competent students from lower social classes make it to the next level while also mediocre students from the upper social classes enter the higher level (Cameron and Heckman, 1998). Thus, as long as it is not possible to control for the unobserved competence development of individuals in educational transition studies, this issue cannot be decided.

Life course researchers have been particularly interested to study whether and to which extent events and states at earlier stages of a trajectory have consequences for its later outcomes (Mayer and Tuma, 1990). Dannefer (1987) introduced the so-called Matthew effect into the literature on the life course. The Matthew effect means that small initial inequalities in a trajectory become magnified over the life span. For example, in modern societies there seems to be a general logic in educational careers that the 'already educated get even more education in the next step' while the 'poorly educated at the same time get less,' so that the difference in education between the two groups gradually increases. The Matthew effect is sometimes also referred to as the cumulative disadvantage/advantage hypothesis (O'Rand and Henretta, 1999). It offers a cumulative explanation of how intracohort inequality is increased over the life course in many life domains. The life course literature also suggests a 'status maintenance' and a 'status leveling' hypothesis. The first one contends that initial inequalities are carried along as individuals move through their life course. The second one points to the possibility of a narrowing of the inequality gap (O'Rand and Henretta, 1999).

Studying the Timing of Transitions in the Life Course

Transitions in the life course often represent discrete changes in states, for example starting a new job or getting married. The timing of these transitions in the life course is often characterized by inertia effects. Inertia is the increasing resistance of an individual to change its position with increasing duration in a state (duration dependence). For example, it is well-known that with increasing job-specific experience the job mobility rate of an individual is generally declining or with increasing time of living in a particular place, the rate of spatial mobility is generally decreasing. The mechanisms responsible for this life course patterns are often cumulative investments into job- or firm-specific human capital or into local 'social capital' (one's social ties) which make it increasingly costly for the individual to become a mover. Sometimes the time dependence in a state has a nonmonotonic shape. For example, it is well-known that the rate of entry into first motherhood has a nonmonotonic pattern across age in modern societies. As women's age increases, the rate of entry into motherhood initially rises, reaches a peak, and then decreases. This bell-shaped rate is often explained by two competing mechanisms: (1) the increasing readiness of individuals to enter into motherhood and (2) the probability of the individual to meet a single partner of the opposite sex. At younger ages, there are many unmarried singles on the marriage market in the relevant age range. Then, some of these young men and women marry as they are getting older. With increasing age, however, it is also increasingly difficult to meet an unmarried individual of the opposite sex at the relevant age band. Thus, the marriage rate is at first increasing with an increasing readiness, reaching a peak, and then decreasing with an increasingly difficult marriage market (Blossfeld and Huinink, 1991).

Studying the Effects of Early and Late Life Course Transitions

Life transitions often are associated with societal age norms that create expectations when a life course transition ought to occur in an individual's life (Carr, 2008). They provide a kind of social clock or timetable for important life events (such as the age of completing education, entering the labor market, or having a first child, etc.). With regard to certain life transitions, individuals might be 'early,' 'on-time,' or 'late.' Age norms, connected with social rewards and punishments, exert pressure on individuals to hasten or delay a certain transition and thus encourage age conformity of life course transitions.

Studying the Sequence of Multiple Life Course Transitions

Life course studies indicate that normative sequences exist with regard to various life course transitions. For example, Hogan (1981) argued that as a result of general societal norms, individuals move from school to work and then to marriage as well as parenthood. In order to satisfy this sequencing norm, young adults will be less likely to enter

parenthood before they have finished schooling. In addition, individuals enrolled in education may consider themselves not economically ready for marriage and motherhood. Thus, the completion of education is expected to count as an important prerequisite for entering into parenthood. Indeed, many life course studies document that women's increasing delays of entry into first marriage and motherhood are to a large extent connected with their longer educational participation (Blossfeld and Huinink, 1991).

Studying the Effects of Parallel and Interdependent Processes on the Life Course

From a causal-analytical point of view, the dynamic study of parallel and interdependent processes is one of the most important advances of life course research (Blossfeld et al., 2007). These parallel and interdependent processes can operate (1) at the level of individual's different domains of life (e.g., one may ask how an individual's job career influences his/her family trajectory; see Blossfeld et al., 2005); (2) there may be parallel processes at the level of some few individuals interacting with each other (e.g., one might study the effect of husband's career events on his wife's labor force participation); (3) there may be parallel processes at the intermediate level (e.g., one can analyze how organizational growth of a firm influences career advancement or how changing household structure determines women's labor force participation; see Blossfeld and Hofmeister, 2006); (4) there may be parallel processes at the macro level (e.g., one may be interested in the effect of changes in the business cycle on family formation or individual career advancement); and (5) there may be any combination of such processes of type (1)–(4). For example, in the study of life course, cohort, and period effects, processes at different levels can be measured and included simultaneously in a multilevel analysis (Blossfeld, 1986).

Interdependent Trajectories at the Level of the Individual

At the level of the individual, events in one trajectory are often presumed to influence the transitions in other domains of life and vice versa (e.g., Blossfeld et al., 2007). For example, the economic theory of the family expects that women's rising educational attainment levels and better career resources affect their rate of entry into first marriage and first motherhood (opportunity cost hypothesis). However, life course analyses demonstrated that changes in the level of educational attainment or changes in career resources had little or no effect on women's marital timing. The higher-educated women only marry later because they stay longer in school and therefore delay entry into marriage (sequence norm). Yet, there is an effect of women's educational and career investments on entry into first birth. Because women, and not men, still take primary responsibility for child care in most modern societies. Women therefore work less or even interrupt their careers when a child is born. Therefore, women who have accumulated a high stock of human capital in their life course tend to gradually postpone or even avoid the birth of a first child. This effect is especially pronounced in traditional family systems, where insufficient child care facilities are available, such as those in Southern Europe (Blossfeld, 1995).

Interdependencies in the Process of Spouse Selection (Educational Homogamy)

In most modern societies the participation in higher education has increased dramatically in recent decades – and more so for women than for men. Life course researchers therefore have been especially interested to explore the role of the educational system as a marriage market and to analyze the changes in educational assortative mating induced by educational expansion (Blossfeld, 2009). In their longitudinal analyses they reconstructed the processes of spouse selection in the life courses of single men and women step by step and compared the results across birth cohorts and various countries (Blossfeld and Timm, 2003). These life course studies tried to take into account the dynamic opportunity structures to meet potential partners in the various parts of the educational system. One finding of these longitudinal analyses has been that with increasing duration in the educational system the rate of homogamous marriage is indeed rising. Increasing rates of educational homogamy across cohorts, however, means that social networks are closing to outsiders and that the opportunities of the generation of children are gradually segmenting.

Interdependencies of the Careers of Spouses

Life course researchers have been particularly interested to study linked lives (Elder et al., 2003). For example, they analyzed the effect of husbands' careers on their wives' labor force participation. A comparative analysis of spouses in 13 countries provided evidence that despite substantial improvements in wives' educational attainment and career opportunities, the change in gender specialization within dual-earner couples has been rather modest (Blossfeld and Drobnič, 2001). Gender role change within the family to a large extent has been asymmetric almost everywhere: Housework and child care primarily remained 'women's work,' and husband's participation in housework and child care has not increased substantially (Baxter et al., 2013). The result is often a double burden on women (Evans and Baxter, 2013).

Regardless of wife's job status, husbands in general pursue a life-long continuous employment career. Even in dual-earner marriages, men still tend to define themselves as primary breadwinners, even in cases where their female partners have a similar or even higher occupational status (Blossfeld and Drobnič, 2001). Thus, the career patterns of (married) men are to a large extent independent of career patterns of their partners. Such independence generally does not apply when (married) women's employment trajectories are analyzed in dependence of their husbands. Male partners tend to exhibit a significant influence on their female partners' career patterns in many countries (Blossfeld and Drobnič, 2001). For example, Germany stands out as a country with a particularly traditional division of labor in married couples. In this country, the analysis shows that high career resources of the husband can even suppress wife's career potentials and drive her out of the labor market.

Interdependencies at an Intermediate Level

At the intermediate level, life course researchers might examine how the changing household or organizational structure of a firm determines women's labor force participation in different countries. For example, in modern societies there is

very often a complex association between the age of the youngest child and female labor force participation (Blossfeld and Hakim, 1997; Blossfeld and Drobnič, 2001). The common interpretation is that the care of young children tends to keep mothers at home in conservative welfare states. However, it is also plausible that the lack of jobs encourages women to enter into a stay-at-home marriage. Event history analysis is able to shed light into this complex interdependence.

Dependencies of Life Courses on Processes at the Macro and Global Level

At the macro level of society, life course researchers have been interested, for instance, in the effect of changes in the business cycle on family formation (e.g., Blossfeld and Huinink, 1991). In these studies often effects at different levels are jointly examined. For instance, in the study of life course, cohort, and period effects, processes at the individual level (accumulation of career resources) have been jointly analyzed with two kinds of processes at the macro level: (1) variations in economic entry conditions specific for certain (birth, marriage, etc.) cohorts (cohort effects); and, (2) changes in particular historical conditions affecting all cohorts in the same way (period effects) (Blossfeld, 1986).

More recent studies have also demonstrated that similar processes at the global level have diverse effects on individual life courses in various countries (Mayer, 1997). In all modern countries, the effect of globalization is 'filtered' by domestic institutions and shaping the life course transitions in country-specific ways (Blossfeld, 2009). The globalization impact is most important at the transition from youth to adulthood (e.g., at entry into the labor market and the phase of family formation, Blossfeld et al., 2005). In particular the growing economic and temporal uncertainties lead young people to postpone or even forgo family formation (Blossfeld et al., 2005). Established men in their midlife career, however, are remarkably unaffected by globalization (Blossfeld et al., 2006a). The kind of labor market participation and the different welfare regimes are very important, if the impact of globalization on women's midlife transitions between employment and family are considered in modern societies (Blossfeld and Hofmeister, 2006). Finally, the effects of globalization on late job careers of men and women and their transition into retirement in modern societies are shaped by different pension systems (Blossfeld et al., 2006b).

Event History Analysis

Event history analysis provides an appropriate statistical framework for investigating the various dimensions of life course processes just described.

Basic Terminology

Event history analysis studies transitions across a set of discrete life course states, including the length of time intervals between entry to and exit from these states. The basic analytical framework is a state space and a time axis. The choice of the time axis or clock (e.g., age, experience, marriage duration, etc.) used in the life course analysis must be based on theoretical considerations. An episode, spell, waiting time, or duration–terms that are used interchangeably in the literature–is the time span an individual spends in a specific state. The states are discrete and usually small in number (e.g., single, married, divorced, remarried). The definition of a set of possible states, called the state space, is also dependent on substantive considerations. Thus, a careful, theoretically driven choice of the time axis and design of state space are crucial for a successful life course analysis. These issues are often serious sources of misspecification (Blossfeld et al., 2007).

The most restricted event history model is based on a process with only a single episode and two states (one origin and one destination state) (see Blossfeld et al., 2007: 38pp.). An example may be the duration (or episode) of first marriage until the end of the marriage (for whatever reason). In this case, each individual who entered into first marriage (origin state) started an episode, which could be terminated by a transition to the destination state 'not married anymore.' If more than one destination state exists, these models are called multistate models. They are also referred to as models with competing events or competing risks. For example, the first marriage might be terminated by the event 'death' or the event 'divorce.' If there are repeated events over the life course, these models are called multiepisode models. For example, if we analyze not only first marriages but all marriages of individuals over the life course at once. The individual then moves repeatedly between different states. Thus, in event history analysis, we have often a sample of $i = 1,\ldots,N$ multistate-multiepisode data. A complete description of the data is given by

$$(u_i, m_i, o_i, d_i, s_i, t_i, x_i) \;\; i = 1, \ldots, N$$

where u_i is the identification number of the individual; m_i is the serial number of the episode; o_i is the origin state, the state held during the episode until the ending time of the episode; d_i is the destination state defined as the state reached at the ending time of the episode; s_i and t_i are the starting and ending times, respectively. In addition, there is a covariate vector x_i with time-constant and/or time-changing factors associated with the episode. We always assume that the starting and ending times are coded such that the difference $t_i - s_i$ is the duration of the episode, which is positive and greater than zero.

Censoring

Observations of event histories are often censored. Censoring occurs when the information about the duration in the origin state is incompletely recorded. If the length of time an individual has already spent in the origin state is unknown, the episode is censored on the left. This kind of censoring should be avoided because it is not easy to handle in methodological terms (see Blossfeld et al., 2007: 39pp.). Most life course studies are designed in a way that the processes are observed right from the beginning. Right-censoring on the other hand, is very common. This type of censoring typically occurs in life course studies at the time of the retrospective interview, or in panel studies at the time of the last panel wave. For example, if one is interested in entry into first motherhood, women who are still in their fertile years and have not had a first baby until the interview, have a right-censored episode. This means that

these women might get a first baby later, but we do not know. Because the timing of the interview is normally independent of the timing of the substantive processes under study, this type of right censoring is unproblematic. It can easily be handled with event history methods.

The Dependent Variable

Event history models can be formulated in continuous-time (Blossfeld et al., 2007) or discrete-time (Mills, 2011; Yamaguchi, 1991; Vermunt, 1997). For each point in time (continuous-time models) or for each time interval (discrete-time models), they predict future levels or changes of the transition rate of the dependent process on the basis of states and/or events of other processes in the past. The central concept of event history analysis is the transition rate. Because of the various origins of event history analysis in the different disciplines, the transition rate is also called the hazard rate, intensity rate, failure rate, transition intensity, risk function, or mortality rate. The transition rate describes in detail how the dependent process evolves over time.

If time can be considered to be (approximately) continuous, i.e., when events at least in principle can happen at any point in time, the transition rate $r(t)$ can be interpreted as the propensity (or intensity) to change from an origin state to a destination state, at time t (Blossfeld et al., 2007: p. 36):

$$r(t) = \lim_{t' \to t} \Pr(t \leq T < t' | T \geq t)/(t' - t) \text{ with } t < t'$$

It is important to note that the propensity $r(t)$ is defined in relation to a risk set ($T \geq t$) at t, i.e., the set of units that still can experience the event because they have not yet had the event before t. In other words, the transition rate is a conditional density function, that is, the density function $f(t)$ divided by the survivor function $G(t)$

$$r(t) = f(t)/G(t)$$

where $f(t) = \lim_{t' \to t} \Pr(t \leq T < t')/(t' - t)$ with $t < t'$ and $G(t) = \Pr(T \geq t)$.

If events can only happen within fixed time-intervals, the continuous time axis is arbitrarily split into a series of time intervals $\tau_0 < \tau_1 < \tau_2 < \ldots < \tau_q$, with $\tau_0 = 0$. The number of the time interval then becomes a discrete random variable $T^* = t \Leftrightarrow T^* \in (\tau_{t-1}, \tau_t)$, with $t = 1, \ldots, q$. T^* denotes the time interval, where an event happens. The discrete-time transition rate is then a (conditional) probability,

$$r^*(t) = \Pr(T^* = t | T^* \geq t) \text{ with } 0 \leq r^*(t) \leq 1$$

$r^*(t)$ is the probability that the dependent variable changes from an origin state to a destination state in time interval t under the condition that the event did not yet happen until the beginning of that interval. In the discrete-time model the transition rate $r^*(t)$ is therefore a conditional probability function, where the probability function $f^*(t)$ is divided by the survivor function $G^*(t)$

$$r^*(t) = f^*(t)/G^*(t)$$

where

$$f^*(t) = \Pr(T^* = t)$$

and

$$G^*(t) = \Pr(T^* \geq t)$$

For small time intervals (e.g., when life histories are recorded on the basis of months) continuous-time models can be approximated by discrete-time models (Blossfeld et al., 2007: p. 37). The estimation results of equivalent time-continuous and time-discrete event history models $\Pr(T^* = t)$ then yield very similar coefficients.

Statistical Models

The central idea in event history analysis is to make the continuous-time transition rate $r(t)$ or the discrete-time transition rate $r^*(t)$ dependent on concepts of time (e.g., duration t) and on a set of time-constant x or time-dependent $x(t)$ covariates:

$$r(t) = g[t, x, x(t)] \text{ or } r^*(t) = g[t, x, x(t)]$$

The causal interpretation of the transition rate requires that we take the temporal order in which the processes evolve very seriously. In the continuous-time mode, at any given point in time t, the transition rate $r(t)$ can be made dependent on conditions that happened to occur in the past (i.e., before t), but not on what is the case at t or in the future after t. Equivalently, in the discrete-time model, in any given time interval t, the discrete-time transition rate $r^*(t)$ can be made dependent on conditions that happened to occur before the beginning of interval t, but not on what is the case in time interval t or after time interval t.

There are several possibilities to specify the functional relationship $g(.)$ between covariates and the transition rate in continuous-time event history analysis (see Blossfeld et al., 2007). First, the 'exponential model,' which normally serves as a kind of baseline model, assumes that the transition rate can vary with different constellations of time-constant covariates, so that the rates are time-constant, too (see Blossfeld et al., 2007: 87pp.)

$$r(t) = \exp(\beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n) = \exp(X\beta)$$

where β_0 is a constant, X is the row vector of covariates, and β is a corresponding column vector of coefficients.

In most life course applications of transition rate models, the assumption that the forces of change are constant over time is, however, not justified. This is particularly true, if we are interested in causal relationships which relate changes (or events) in some (explaining) processes to changes (or events) in a dependent life course process. In our view, the most important step forward in event history analysis has been to explicitly measure and include time-dependent covariates in transition rate models. In such cases, covariates can change their values over process time. Time-dependent covariates can be qualitative or quantitative, and may stay constant for finite periods of time or change continuously (see Blossfeld et al., 2007: p. 128). Time-dependent covariates can be included (1) by using a piecewise constant exponential model, (2) by applying the method of episode splitting in parametric or semiparametric transition rate models, and (3) by specifying the distributional form of the time-dependence and directly estimating its parameters using maximum likelihood method.

A first simple and very useful generalization of the 'exponential model' is the so-called 'piecewise constant exponential model.' It allows the transition rate to vary across fixed time periods with period-constant or period-specific effects of covariates (see Blossfeld et al., 2007: 116pp.). The piecewise constant model is particularly helpful when researchers are not in a position to measure and include important causal factors (time-dependent covariates) explicitly or when they do not have a clear idea about the form of the time-dependence of the process, after controlling for important covariates. The basic idea of the piecewise constant exponential model is to split the duration into L time periods.

$$I_t = \{t|\tau_1 < t \leq \tau_{l+1}\} \quad 1 = 1, \ldots, L$$

based on arbitrary split points on the time axis $0 = \tau_1 < \tau_2 < \ldots < \tau_L$, with $\tau_L = \infty$.

The transition rate can then vary over the $l = 1, \ldots, L$ time periods based on the changing period-specific constants β_l (baseline hazard rate)

$$r(t) = \exp\{\beta_1 + X\beta\} \quad \text{if } t \,\varepsilon\, I_1$$

where X is a (row) vector of covariates, and β is an associated vector of coefficients. Note that in this model there is no additional constant in X.

Since causal relationships relate changes (or events) in explaining processes to changes (or events) in a dependent life course process, it is very important to be able to represent the changes of the causal forces in event history models directly. An easy way to do this is to include time-varying covariates $x(t)$ in the 'exponential model' via the method of episode splitting.

$$\begin{aligned} r(t) &= \exp\big[\beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n + \beta_{n+1} x_{n+1}(t) \\ &\quad + \beta_{n+2} x_{n+2}(t) + \ldots + \beta_{n+p} x_{n+p}\big] \\ &= \exp[X(t)\beta] \end{aligned} \qquad [1]$$

where β_1 is the regression constant ($x_1 = 1$). The transformation of the person-spell file into a person-period file through episode splitting is described in detail in Blossfeld et al. (2007: 135pp.).

Another model is the so-called Cox (1972) model, where the baseline hazard rate $h(t)$ is left unspecified. Thus, it is only possible to estimate the effects of the time-constant or/and time-varying covariates, controlling for an unknown baseline hazard rate. This model is also called semiparametric model, since only part of the rate function is parametrically specified, or partial likelihood model, because only part of the likelihood function is maximized (see Blossfeld et al., 2007: 216pp.),

$$\begin{aligned} r(t) &= h(t)\exp\big[\beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n + \beta_{n+1} x_{n+1}(t) \\ &\quad + \beta_{n+2} x_{n+2}(t) + \ldots + \beta_{n+p} x_{n+p}(t)\big] \\ &= h(t)\exp\big[X(t)\beta\big] \end{aligned}$$

Note that in this model there is again no regression constant in $X(t)$.

However, in some applications in life course research, substantive theory or previous empirical research may suggest a specific shape of time or duration dependence of the transition rate. However, time itself is no causal factor. Rather measures of time may serve as proxies for time-changing causal factors that could not be observed directly (see Blossfeld et al., 2007: 182pp.). For example, duration might serve as a proxy for 'the changing amount of marriage-specific investments' in divorce studies. There are different parametric models which are based on specific shapes of the time-dependence. For example, the Gompertz(-Makeham) and Weibull models are able to specify monotonically increasing or monotonically decreasing shapes of the hazard rate. Further parametric models such as the Sickle, the Log-logistic, and the Log-normal models allow to estimate a (at first increasing and then decreasing) nonmonotonic time-dependency (see for more details Blossfeld et al., 2007: 204pp.).

Finally, an important problem of event history analysis is also the issue of unobserved heterogeneity. In this case, the transition rate that is estimated for a population can be the result (a mixture) of quite different transition rates in the subpopulations (see Blossfeld et al., 2007: 247pp.). There have been several proposals to deal with unobserved heterogeneity in time-continuous transition rate models. The basic idea is to incorporate an 'error term' into the model specification. For example, the continuous-time transition rate can be made dependent on an exponential model, the observed (time-dependent) covariates $X(t)$ and a stochastic error term ν, which is e.g., Gamma distributed (see Blossfeld et al., 2007: 256pp.)

$$r(t|\nu) = \exp[X(t)\beta]\nu \quad \text{with } \nu \geq 0 \qquad [2]$$

A likelihood ratio test can then be used to test, whether the transition rate models with and without this unobserved heterogeneity term differ.

In the case of discrete-time models, the estimation of covariate parameters is normally achieved by preparing a period-person data file and then estimating a simple logit model:

$$r^*(t) = \frac{\exp(\alpha_1 x_1 + \alpha_2 x_2 + \ldots + \alpha_n x_n)\exp[\beta(t)]}{1 + \exp(\alpha_1 x_1 + \alpha_2 x_2 + \ldots + \alpha_n x_n)\exp[\beta(t)]} \qquad [3]$$

or

$$r^*(t) = \frac{ab(t)}{1 + ab(t)} \qquad \begin{aligned} &\text{with } a = \exp(\alpha_1 x_1 + \alpha_2 x_2 + \ldots + \alpha_n x_n) \\ &\text{and } b(t) = \exp[\beta(t)] \end{aligned}$$

If $b(t) = \exp(\beta_0)$, the logit model estimates an exponential model, if $b(t) = \exp(\beta_0 + \beta_1 t)$ it estimates a Gompertz model, if $b(t) = \exp(\beta_0 + \beta_1 \ln t)$ it estimates a Weibull model. A piecewise constant model is estimated for $b(t) = \exp(\beta 1)$ if $t \,\varepsilon\, I_1$ where changing period-specific constants $\beta 1$ can vary over the l = 1,…, L time periods.

Application Example

In order to demonstrate the strength of life course analysis with event history models in a substantive context, we estimate the rate of dissolution of first marriage for East and West German women. Using a subsample of retrospective life histories of 3957 married women born in East and West Germany from the NEPS, we estimate a period-specific discrete-time event history logit model with time-constant and time-varying covariates. The NEPS collects dates of transitions and events on a monthly basis. For our analysis, we define for each woman a spell starting at entry into first marriage and ending at the time of its dissolution. For women, who do not experience a marital dissolution until the time of the interview, we censor the spells

on the right. The spells are also right-censored for women whose husband passed away. This leads to a person-oriented spell data set, where each married woman in the sample has exactly one record of data. We have then transformed this person-level data set into a person-period data set using the method of episode splitting (Blossfeld et al., 2007), in which each woman has multiple records – one for each month. Such a person-period data set allows an easy integration of time-varying covariates because the covariates can change their values across each of the person-month records.

In our longitudinal analysis, we are using the following covariates:

1. *Duration of marriage* (time-dependent covariate). We include dummy variables distinguishing eight periods of marriage duration;
2. *Place of birth* (time-constant covariate). We use the dummy variable 'East Germany' to identify women born in East Germany, women born in West Germany are the reference category;
3. *Historical periods* (time-dependent covariates). To distinguish the periods before and after unification in our analysis, we use the dummy variable 'Period after 1990.' The reference category is the 'Period until 1990.' We include also an interaction dummy variable 'East*Period after 1990' to estimate the effect of the 'German unification' on East German women;
4. *Husband's educational attainment* (time-constant covariate). In order to model husband's highest educational attainment, we distinguish seven educational degrees. We then attach the average number of years that are necessary to achieve these degrees;
5. *Wife's educational attainment* (time-dependent covariate). Each time when a woman attains a higher level of education, the educational attainment level is adjusted. We distinguish seven educational attainment levels and express each degree as the average number of years necessary to achieve it;
6. *Partner's relative levels of education* (time-dependent covariates). In order to model the relative resources of partners, we introduce two dummy variables indicating whether a woman has a higher or lower level of education than her partner (ref. category: both partners have the same educational attainment level);
7. *Premarital states* (time-constant covariates). We introduce three dummy variables to control if women cohabited with their husband at the time of marriage (ref. category: women who did not cohabit with their husband at the time of marriage), were pregnant at the time of marriage (ref. category: women who were not pregnant at the time of marriage), or have had a child before marriage (ref. category: women who had no child before marriage);
8. *Age at first marriage* (time-constant covariates). To include the age at first marriage into our analysis we distinguish five age categories;
9. *Age of the youngest child* (time-dependent covariate). We include the age of the youngest child by distinguishing seven time-dependent dummy variables.

Table 1 Estimation results of a discrete-time event history model for the dissolution of women's first marriage in Germany

Covariate	*Coefficient*	
Duration (in years)		
0–1	−9.286	c
2–3	−7.328	c
4–5	−6.957	c
6–7	−7.149	c

[b] $p < 0.01$.
[c] $p < 0.001$.
$n = 3957$.
Source: Own computations based on the NEPS data.

Table 1 shows the results of our discrete event history analysis of women's dissolution of first marriage in Germany including time-varying and time-constant variables. In order to test whether the duration of the first marriage has an effect on divorce, we include information on the duration of first marriage into our analysis. The results show a nonmonotonic bell-shaped pattern of the duration of marriage on divorce. In other words, the rate of dissolution increases up to the fifth year and then decreases.

To analyze the divorce rate in East and West Germany before and after German unification, we include dummy variables to control the place of birth (East vs West Germany), historical periods (before and after German unification), and

an interaction term 'East*Period after 1990.' The results show that there is a declining divorce rate in East Germany after the German unification because of the high level of uncertainty in the transition process from socialism to capitalism.

Table 1 also shows that a higher educational attainment level of the husband stabilizes the marriage, while a higher educational attainment level of the wife has a destabilizing effect. If we compare the relative resources of husband and wife, we find that only homogamous marriages are more stable.

If we include information on premarital cohabitation, childbirth before marriage and pregnancy at the time of marriage into our model, our results show that premarital cohabitation and childbirth before marriage have a destabilizing effect on marriages. Being pregnant at the time of marriage has no effect. We also include information on the age at first marriage. The result shows that marriages are more stable the older the woman is at entry into first marriage. Finally, we include information whether a couple has children and the age of the youngest child into our example analysis. Couples who have a baby younger than 1 year have the lowest divorce rate. The divorce rate then increases with the age of the youngest child and rises above the divorce rate of couples without children. If we control for unobserved heterogeneity, the results of this analysis do not change.

Life Course Criminology

Marvin D Krohn, Molly Buchanan, and Andrea Davis, University of Florida, Gainesville, FL, USA

Abstract

The life-course perspective on crime recognizes it is essential that we view the causes and consequences of criminal behavior throughout individuals' developmental stages. In this article, we review the general conceptual foundation of the life-course perspective. We illustrate the use of this perspective by briefly reviewing four specific theories. Analytical tools to examine intraindividual trajectories are also reviewed. We conclude by suggesting future conceptual and methodological directions to advance the life-course perspective.

Theories of crime were primarily developed to explain the onset, prevalence, and frequency of adolescent delinquency. To an extent, this made pragmatic sense because official data revealed that, for the most part, the onset of arrests did not occur until the early adolescent years and reached the peak in prevalence at ages 15 through 17 years. However, the recognition that there was a small group of 'career offenders' who disproportionally contributed to the prevalence of serious crime and were likely to continue their offending into the adult years broadened our theoretical and research foci to incorporate what happened with these offenders as they transitioned from adolescence to young adulthood. Very quickly, we came to the conclusion that those who disproportionally contributed to the crime problem by committing frequent and serious criminal behaviors and had criminal careers of longer duration than less serious offenders were also precocious in their criminality, beginning their offending at younger ages. Hence, it became critical that we extend our focus to the childhood years. To do so would require a conceptual framework that addressed the full span of a person's life. Such a vantage point would allow us to not only assess individuals' criminal histories but also explore other aspects of individuals' lives and assess how those aspects both impacted and were impacted by their criminal behavior. That conceptual framework has come to be known as the life-course approach.

The life-course approach provides a framework within which we can examine how people develop through the various stages of their lives. In doing so, the focus is on both stability and changes that occur in behavior and attitudes, the causes and consequences of that stability or change, and the interrelationships among different trajectories or pathways that characterize the life course. As such, rather than focusing on interindividual differences to discern patterns that may reflect the causes of behavior, the life-course approach emphasizes intraindividual stability and change to determine how both selection and socialization factors impact the life course. Within this broad conceptual approach, separate theoretical statements have been offered. While differing on some specifics of what they posit as important in describing and understanding human development, all of these theories are commonly concerned with the interweaving of trajectories representing different arenas of one's life and the important changes or transitions that occur during the life course.

In this article, we examine the conceptual bases of a life-course approach. We select four theoretical perspectives to review as illustrations of how life-course concepts have been used to account for the causes and consequences of crime. We also examine some of the unique analytical tools that have been developed and used to examine intraindividual change. This article concludes with suggestions for areas for future development.

The Conceptual Basis of the Life-Course Approach

The life-course approach to the study of human behavior conceptualizes the life course as a sequence of age-graded stages. The course through which a person traverses these stages within a domain of behavior is referred to as a trajectory (Elder, 1985). People traverse multiple trajectories such as educational, family, and work trajectories. In addition, behaviors such as criminal involvement can also be seen as trajectories. Importantly, the life-course perspective emphasizes the interconnectedness among trajectories. That is, the perspective is particularly interested in how the movement along one trajectory affects the path of another trajectory.

As people move along a particular trajectory, they will make transitions. A transition is a life event that is embedded within a trajectory and often results in "changes in state that are more or less abrupt" (Elder, 1985: pp. 31–32). For example, graduation from high school can be considered a transition in one's educational trajectory that may not only influence the course of that trajectory but may also influence what happens in the person's work life and family relationships. Related to the concept of transitions is the term 'turning points.' Turning points refer to particularly significant changes in the direction of one's life course (Elder, 1985). Getting married is a transition that has been conceptualized as a potential turning point in the criminal behavior trajectory (Sampson and Laub, 1993). That is, marriage will often deflect a person who is on trajectory of continuing crime away from problematic behavior and more toward conforming behavior.

The timing and sequential order of transitions can be consequential. There are cultural expectations for the appropriate timing of transitions, which, when violated, may cause problems for the person. We are expected to stay in school at

least through high school graduation. Quitting school prior to that time may have serious ramifications for the life course. Other off-time transitions such as having a child during one's teenage years often impact one's educational and work-related trajectories (Krohn et al., 1997).

The above review of key concepts in the life-course approach provides a foundation for further exploring the theoretical perspectives directed at explaining criminal behavior from a life-course perspective and the methodologies that have been developed to analyze these issues.

Life-Course Theories of Crime

The key concepts and general orientation of the life-course approach have been incorporated into several theories focusing specifically on the causes and consequences of criminal behavior (see Farrington, 2005). In this section, four theories that have had an important impact on the field are briefly described. Any explanation of what transpires across the life course is typically going to be complex; therefore, these theories cannot be presented fully in this brief article. Rather our emphasis is on what distinguishes one theory from the others.

Moffitt's Dual Taxonomy Theory

Drawing from concepts in both developmental and neuropsychology, Terrie Moffitt introduced a dual taxonomic theory to explain the age–crime curve (Moffitt, 1993). This developmental theory asserted that indications of persistent antisocial behavior could be detected during childhood. What distinguishes this theory from other general or developmental models is that it proposed that not all offenders are the same and not all antisocial behaviors are caused by the same explanatory factors. More specifically, the theory identifies two unique 'offending groups,' or trajectories, that can be differentiated based on two factors: the age when conduct problems begin and the trajectories of those problems (Moffitt, 1993). The two offending groups are referred to as 'early starters,' or life-course persistent offenders (LCPs), and 'late starters,' or adolescence-limited offenders (ALs).

There are significant differences between LCPs and ALs. Within the late-starter group, antisocial behavior typically begins and ends during adolescence (hence the group name of ALs); thus, their delinquency career is brief (Moffitt, 2003). Moreover, adolescence-limited offending is said to be both situational and temporary. Moffitt suggests that a maturity gap – the time period after puberty when biological maturation has occurred, but youths do not yet have access to 'adult' privileges and resources – might contribute to the normalization of antisocial behavior. During this maturity gap, ALs may mimic the behaviors of LCPs in an attempt to show independence from parents or accelerate social maturity (Moffitt, 2003). But, because their early developmental years were prosocial and they do not have the neuropsychological deficits characteristic of LCPs, most ALs desist from crime and adopt a prosocial lifestyle upon entering young adulthood. By young adulthood, individuals typically have gained more independence from parents, leaving little reason for them to further mimic LCP behaviors.

Contrary to ALs who desist from delinquent behaviors as they gain independence, LCPs are characterized by continuity of antisocial behavior. That is, their delinquency careers begin in early childhood, persist into adulthood, and are stable over the life course. According to Moffitt, LCPs often have neuropsychological deficits that impede their verbal development. In addition, LCPs may have early emotional and behavioral problems such as bad temperament or hyperactivity (Moffitt, 1993). These early deficits may adversely influence parenting quality, as dealing with such children can often be difficult. Moreover, the inheritance of many of these antisocial qualities has been hypothesized, further suggesting that biological parents of LCPs may be poor candidates for effectively handling and coping with their children's problem behaviors. Moffitt uses the term 'cumulative continuity' to suggest that early problems in the family can lead to continuing problems in school and other arenas in which LCPs interact. In addition, 'contemporary continuity' or the effects of deficits continue to be felt throughout different development stages. These high-risk neuropsychological and environmental interactions during the formative first two decades of life eventually develop into disordered personalities characterized by antisocial behaviors that carry on into midlife (Devers, 2011).

Sampson and Laub's Age-Graded Theory

Growing out of Hirschi's (1969) bonding theory, Sampson and Laub (1990) introduced the age-graded theory of informal social control to developmental criminology. This theory aimed to move away from what the authors believed were limitations of prior life-course research, including the adolescence focus and viewing desistance in a reductionist 'criminal to noncriminal' framework. Instead, Sampson and Laub viewed crime from childhood to adulthood, using individuals' differences and social ties to explain their initiation and desistence from criminal behavior. Although they recognized continuity in deviant behavior, they theorized that high-quality social ties in adulthood could deflect criminal behavior trajectories toward conforming behaviors in adulthood (Sampson and Laub, 1990).

The age-graded model of informal social control predicts that individuals with more social capital, high-quality marital bonds, and secure employment are more likely to desist from criminal behavior. Thus, the basic premise of this model is that, in spite of the continuity of criminal behavior, turning points, such as getting married, can change an individual's criminal trajectory and result in desistance from crime (Laub and Sampson, 1993). This age-graded model recognizes the influence of childhood behaviors while also highlighting the importance of major life transitions, or turning points, in explaining criminality over the life span.

Sampson and Laub (1992) delineated different stages of the life course that help provide context for their theory. From early childhood up to age of 18 years, structural problems such as low family socioeconomic status or parental divorce, in addition to individual differences in temperament, are predicted to influence whether juveniles become delinquent and how they

form bonds in adulthood. During adolescence specifically, unhealthy relationships with parents, attachment to delinquent peers, and low levels of attachment to school are all expected to lead to juvenile delinquency. Ages 18 through 25 yeas represent the stage at which deviant activity can greatly threaten the development of informal social bonds, with possible incarceration and its subsequent stigma, making attachment to prosocial bonds even more difficult in adulthood. Therefore, career criminality may develop from ages 25–45 years due to individuals' failure to reestablish prosocial attachments. In contrast, individuals who successfully develop prosocial attachments, whether through stable employment, family bonds, or high-quality marriages, will no longer commit crime because of these informal mechanisms of social control (Devers, 2011).

Thornberry and Krohn's Interactional Theory

Terence Thornberry (1987) was one of the first criminologists to emphasize the importance of assessing how potential predictors of delinquency and crime might operate differently at different stages of the life course. He began by presenting three models depicting the causal processes of crime during early, middle, and late adolescence, respectfully. He elaborated on a basic social control model (Hirschi, 1969) by incorporating concepts from both social learning theory and social structural perspectives. In doing so, he emphasized three aspects of his theory: (1) the need to examine how the variables included in interactional theory may vary by stage of development, (2) the incorporation of the construct of structural disadvantage as antecedent to the elements of the social bond, and (3) the recognition that some of the variables may be reciprocally related to one another.

In part, because of his continuing work on the Rochester Youth Development Study (RYDS), a longitudinal panel analysis of high-risk adolescent youths, which eventually developed into both a follow-up into the adult years and a study of the children of the original target subjects, Thornberry further developed his theory (Thornberry and Krohn, 2001, 2005), transforming it into an explanation that covered the life course.

In addition to the three building blocks of interactional theory listed above, Thornberry and Krohn (2005) added the premise of proportionality of causal influences. In recognizing that delinquency and crime had multiple causes and that not all causes had to occur in order for a particular outcome to result, Thornberry and Krohn focused on the magnitude of a causal force as being critical for producing an outcome. The concept of proportionality would then suggest that "as the magnitude of the causal force increases, the person's involvement in crime a) becomes more likely and b) increases in severity." The concept of proportionality has implications for how their perspective differs from Moffitt's dual taxonomy theory. According to Thornberry and Krohn (2005), there are not two types of offenders, but rather the range in the magnitude of causal influences results in some offenders beginning at an earlier age, committing more serious and frequent crime, and having a longer career than other offenders.

Taking into consideration how multiple causal factors play potentially different roles at different stages of development results in a somewhat complex theory that can account for the onset, duration, and seriousness of criminal behaviors. It is not possible to adequately describe the full range of the theory in this article, so we will concentrate on the onset of delinquency in order to illustrate some of the dimensions of the theory.

Thornberry and Krohn (2005) hypothesize that the early onset of antisocial factors is a result of individuals' characteristics, problematic parenting, and positions in the social structure. The early manifestation of antisocial behaviors during toddlerhood and preschool years only results if the interaction of these three areas is of great magnitude (proportionality). The uncoupling of these three deficits weakens the causal mechanisms and is likely to delay the onset of problematic behavior until the social networks widen when the child goes to school. Now whatever deficits the child has are more likely to emerge, resulting in the onset of antisocial behavior. School and peer factors become increasingly important as the child ages. Early participation in antisocial behavior, of course, impacts performance in school and the choice of friends as well (bidirectional causality). Youths who have strong parental and school support will delay the onset of any delinquent behaviors until the adolescent years. Then the quest for independence, a necessary prerequisite for the successful transition into adulthood, may cause stress in the lives of some youths, creating more reliance on peers and, at least for some, engagement in delinquent behavior.

Thornberry and Krohn (2005) go on to account for both the continuity in delinquent behavior and the potential for change in those behaviors. The importance of the magnitude of deficits and the impact of prior behaviors on subsequent life chances and continuing criminal behavior are emphasized. For example, in describing continuity of criminal behavior among those who had an early onset, Thornberry and Krohn (2005: p. 198) state: "In brief, we hypothesize that individuals who initiate antisocial behavior at very young ages are more likely than average to persist because the causal factors are likely to remain in place and because early involvement in antisocial behavior generates cumulative and cascading consequences in the person's life course." For those whose deficits are uncoupled, change toward more conforming behaviors is more likely.

Farrington's Integrated Cognitive Antisocial Potential Theory

David Farrington's (2003) research using the Cambridge Study in Delinquent Development identified numerous risk factors of delinquent behavior and the consequences of such behavior throughout the life course of the study's respondents. Based on the voluminous findings from that study, Farrington developed (1992) and then revised (2005) his integrated cognitive antisocial potential (ICAP) theory.

The key construct in his theory is antisocial potential (AP). AP is the potential individuals have to commit antisocial behaviors. Farrington further distinguishes between long-term AP and short-term AP. Long-term AP is due to some combination of impulsiveness, strain, socialization processes, and life

events, while short-term AP depends on situational factors (Farrington, 2005: p. 76).

Farrington (2005) also identifies a set of risk factors that predicts the levels of both long-term and short-term AP. The factors suggested to predict long-term AP include those typically identified in developmental life-course theories related to social structural position, parenting, socialization, life events, and individual factors. Short-term AP is dependent on emotive states (bored, angry), the influence of male peers, and opportunities to commit crime.

The commission of a crime is dependent on the coming together of long-term and/or short-term AP with cognitive processes. Cognitive processes include a constellation of thoughts a person might have regarding the costs and rewards of behaviors and the probabilities of achieving desired outcomes. In turn, the benefits of committing a behavior are somewhat dependent on anticipated approval from parents, peers, and partners. Farrington recognizes that the different combinations of long-term AP, short-term AP, and various cognitive processes may differ for different types of people but does not speculate on those dynamics.

The ICAP theory is a compilation of Farrington's research findings that focused primarily on establishing the risk factors for delinquent and criminal behavior. The causal processes that may explain why those factors present risk for criminal behavior have not been presented in his theory. Further development of those interconnections may provide a more thorough explanation of crime across the life course.

Methodological Advances and the Life-Course Approach

As outlined above, a main premise of the life-course approach is age-graded stages of development across various life domains. These stages can be further conceptualized as trajectories or long-term developmental patterns throughout the life course (Elder, 1975). A compendium of longitudinal data sets has emerged in recent years along with subsequent advances in methodological techniques. Researchers now have the enhanced ability to statistically 'look back' and simultaneously model respondents' developmental trajectories while considering the impact of theoretically relevant covariates. The following section describes a few of these methodological advances, focusing especially on semiparametric group-based trajectory modeling (GBTM) (Nagin, 2005).

Historical Background

During the criminal–career–age–crime curve debates of the 1980s, Blumstein et al. (1988) contended that offenders' patterns of criminal continuity and discontinuity were not static but, rather, were dynamic and varied over time. As such, these scholars posited that the classic, aggregate age–crime curve masked important differences in the prevalence and incidence of criminal involvement. This position was strongly debated by Gottfredson and Hirschi (1988), who argued in support of the static nature of offending behavior. Moreover, as proponents of the classic age–crime curve, Gottfredson and Hirschi (1986) posited that the pattern revealed at the aggregate level would be similar to patterns revealed from alternative individual-level analyses. Said differently, the authors argued that *all* individuals followed the rise, peak, and fall pattern seen in the aggregate. However, the significance of individuals' different levels of crime participation and frequency of criminal involvement became increasingly recognized with groundbreaking longitudinal analyses using data from the Philadelphia birth cohort study (see Wolfgang et al., 1972). These findings revealed that, over time, a *small* group of offenders was responsible for the *most* serious offenses. More importantly, these longitudinal results revealed patterns and facets of criminal careers not previously apparent from cross-sectional analyses.

The life-course approach has generated an increasingly accessible database and methodological techniques with which to examine theoretical implications. We are no longer limited to identifying and interpreting correlations between behaviors and later outcomes. Rather, exploration into *how* behaviors are connected throughout the life course and their influence on the continuity or change of antisocial behaviors can now be more accurately assessed.

Methodological Techniques Popular to the Life-Course Approach

Increased use of longitudinal designs and analyses has resulted in more accurate estimation of individuals' behavioral patterns (Sampson and Laub, 1992). Constrained to the statistical techniques available, early longitudinal researchers ran the risk of potentially 'underfitting' complex data sets and leaving certain developmental patterns undiscovered. However, recent advances in the methodological tools available allow researchers to better capture the connectedness of behaviors over time.

Three specific methods have been chosen for comparison in this article: hierarchical linear models (HLM), latent growth curve models (LGCM), and GBTM. All the three methods have been used to achieve a "common analytical objective" (Nagin and Odgers, 2010b: p. 114) of identifying shapes of developmental trajectories as functions of age or time and assessing the variability of identified trajectories within a population (Nagin, 1999; Nagin and Odgers, 2010b). Deciding which technique is best suited for analyses is typically guided by the theoretical framework, the research question at hand, and, especially, the assumptions made by each of the three methods (Curran and Bollen, 2001). This section gives an overview of important differences between these three models, ultimately providing a more thorough review of GBTM and its advantages for developing and modifying life-course theories.

Oft mentioned as alternatives to GBTM (Nagin and Tremblay, 2005b), HLM or LGCM offer multilevel approaches for modeling repeated measures to assess individuals' change over time. The two methods allow models of individuals' unobserved (latent) patterns, or trajectories, to be estimated using either manifest, observed measures in HLM (Raudenbush et al., 2004) or latent constructs, as is the case

with LGCM (Loehlin, 2004). Likewise, both methods assess differences in within-person, or intraindividual change over time, with outcomes revealing mean developmental patterns within a population as well as individuals' variability from these average patterns (Preacher et al., 2008).

HLM analyses assess variables across different levels. Initially, unconditional models are estimated to separate the fixed and random effects and provide both intra- and interindividual variance estimates. Level 1 variables address within-person measures that can vary over time, while Level 2 measures reflect independent variables that can be used to predict or explain variability in within-person changes between individuals (Raudenbush and Bryk, 2002). The unconditional model estimates are used to calculate intraclass correlations (ICCs). The ICCs are interpreted as differences attributable to the Level 2, *inter*(between)-individual measures. Further analyses include regression of Level 1 factors onto Level 2 variables. Such analyses result in cross-level interactions between the levels. These interaction terms are used to evaluate differences in individuals' developmental trajectories as a function of their Level 2 covariates. In sum, HLM allow for assessing the influence of between-person differences on within-person change over time (Raudenbush and Bryk, 2002).

Despite many similarities to HLM, LGCM focus on latent, unobserved variables, or growth factors, that may shape and influence the population's mean and variances for an outcome (Bollen and Curran, 2006). Like in HLM, initially estimated unconditional models provide the shape of developmental trajectories using the population mean growth and different rates of change. Instead of estimating variables by levels, LGCM measure growth factors at multiple times then relate those factors to other influential covariates (Bollen and Curran, 2006). Overall, LGCM have been touted as being more flexible than HLM, specifically better handling measurement error, reducing bias, and detecting main effects (Bollen and Curran, 2006; Muthen and Asparouhov, 2011). On the other hand, HLM have been found to provide more accurate estimates of cross-level interactions.

While basic HLM or LGCM share many similarities, more distinct differences exist between them and GBTM models. These differences are especially important when the empirical goal is identifying distinct, unique developmental patterns within a population. First, both HLM and LGCM assume that developmental patterns are distributed continuously. Such a distribution suggests that all individuals within a population move along the same, general development pathways, with their individual trajectories increasing or decreasing over time but following the same general shape or pattern (Nagin and Tremblay, 2005a). GBTM takes a very different approach, allowing for situations where estimated developmental pathways may not 'fit' or follow one common shape or growth pattern (Nagin and Tremblay, 2005a). GBTM's different approach to modeling developmental patterns – assuming individuals within a population can be stratified into homogenous clusters that may follow differently shaped pathways – makes the method a prime technique for allowing unique, distinct developmental trajectories to emerge from a population (Nagin, 1999, 2005). Another strength of GBTM is the decreased subjectivity by which researchers identify clusters of individuals on similar developmental trajectories. While HLM and LGCM employ a more ad hoc style of classifying groups *prior* to estimating developmental trajectories, GBTM provides statistical output for further assessment *after* the identification of trajectory groups (Nagin, 1999, 2005). These posterior probability statistics can be used to guide more precise classifications of groups and are an important advantage to be aware of when considering the best technique to identify distinct intraindividual developmental trajectories.

GBTM and Life-Course Theories

With the continuity of human development central to life-course theories, it is important to use analytical techniques that can account for continuous unfolding of behaviors and within-person changes in criminal involvement over time (Bushway et al., 2003; Nagin, 2005; Thornberry and Matsuda, 2011). As such, the use of GBTM in life-course criminology is strengthened by its allowance for variations in rates at which individuals move along developmental trajectories as well as permitting individuals' trajectories to differ by developmental stages, times, or ages (Krohn et al., 2013). Furthermore, by identifying rather than assuming patterns of antisocial development within a population, GBTM has been an invaluable tool in answering the types of questions asked by life-course criminologists (Nagin and Odgers, 2010a).

As an example, Moffitt's (1993) dual taxonomy model suggests two clear, potential developmental offending paths, with individuals' age of onset as the integral consideration for classifying them as ALs or LCPs. Alternatively, other life-course theories, such as Thornberry and Krohn's (2005) interactional theory, do not model such strict classifications of offending groups. Using GBTM to address empirical questions stemming from these life-course theories, researchers have found support for some theoretical contentions but also revealed unexpected developmental patterns of antisocial behavior (i.e., offending groups beyond ALs and LCPs) (Farrington, 2005; Nagin and Tremblay, 2005a). These studies have certainly established variation of individuals' offending patterns over time, showing differences by age of onset, severity of antisocial behavior (i.e., frequency, prevalence), and timing of desistence (Krohn et al., 2013; Piquero, 2008). A comprehensive review of research using different longitudinal data to estimate patterns of offending behavior over time reveals an average of four offending groups (Piquero, 2008).

For illustrative purposes, **Figure 1** presents the results from one study that has estimated respondents' (aged 13–22 years) offending trajectories. Using data from the RYDS, Bushway et al. (2003) find a best-fitting model of seven distinct trajectory groups. These trajectories reveal unexpected patterns, for example, one noteworthy group of 'late bloomers' (group P3). Distinguishing late bloomers from other offending trajectories is their unexpected age of onset when older, as well as their increasing severity of antisocial behaviors (Bushway et al., 2003; Krohn et al., 2013). For a certain period, late bloomers are even shown to surpass the

Figure 1 Rochester Youth Development Study offending trajectories estimated with GBTM (Bushway, S.D., Thornberry, T.P., Krohn, M.D., 2003. Desistance as a developmental process: a comparison of static and dynamic approaches. Journal of Quantitative Criminology 19, 129–153.).

offending patterns displayed by high-level chronics (Bushway et al., 2003; Krohn et al., 2013).

The unearthing of this late-bloomer group using GBTM encourages theoretical explanation and advancement, with scholars already offering reasons for late-bloomer groups. Recent efforts include suggestions that the late-bloomer trajectory is a reflection of social changes – specifically the timing of certain developmental events (i.e., careers, marriage, parenthood) coming at a later age than they did in prior decades (Mata and van Duhlmen, 2012).

Important Considerations for GBTM

In sum, because no extant theory clearly or accurately outlines how many developmental trajectories should exist in a population, GBTM is an asset for scholars attempting to identify such patterns and further develop theoretical propositions. The following are key considerations when applying GBTM. First, groups are not to be considered as literal representations; they are estimates and are theory driven. Developmental trajectory groups are latent strata or clusters of individuals with similarities. These latent strata groups are sometimes referred to as 'statistical fictions,' suggesting the groups *do* exist in the best-fitting model of the data (i.e., there *is* an LCP group of offenders), but the best-fitting model is still an estimate of the *true* population parameters (Nagin and Tremblay, 2005c). Secondly, once trajectories are identified, posterior probabilities can also be used to assess precision of group membership. These posterior probabilities can also be used to classify groups and allow for better description of the characteristics, or profiles, of clusters following different developmental patterns. In addition to these key features, research focusing on GBTM or more general latent class models notes that such analyses are sensitive to the data being utilized, with longer follow-up lengths (i.e., more waves of data) and environmental exposure (i.e., incarcerated versus in the community) impacting trajectories' shapes (Eggleston et al., 2004; Sampson and Laub, 1993). As such, GBTM and related techniques are increasingly combined with other statistical techniques such as propensity score matching (e.g., see Haviland et al., 2007; Ward et al., 2013) to better assess causal relationships or dual trajectory estimation to assess contemporaneous, or comorbid events over the life course.

Future Directions

The recognition that to fully understand the onset, duration, seriousness, continuity, and desistance of crime requires a full examination of what occurs throughout the life course is a relatively recent insight. The life-course approach to the study of crime is still in its early developmental stage. This brief overview of major concepts, theories, and analytical tools used in the life-course perspective touches on only some of the major themes of the approach and, frankly, fails to provide an appreciation for the complexity of examining crime across the life course. While there has been progress in beginning to explore issues related to the trajectory of criminal behavior, there is still much to be done before a true understanding of both the continuity and change in crime and the effects it has on other life-course trajectories can be accomplished. In the remaining paragraphs, we offer a few suggestions for future work on crime across the life course.

To date, much of the conceptual work on crime across the life course has focused on the degree to which there is continuity versus change in criminal behavior. For example, Moffitt's

dual taxonomy approach emphasizes continuity of crime for LCPs. Factors such as neurological deficits set in motion a sequence of consequences that result in child conduct disorders leading to juvenile delinquency and continuing crime into adulthood. Sampson and Laub's age-graded theory emphasizes the role played by adult social bonds in changing the trajectory of crime. Oftentimes, the debate on the degree of overlap between continuity and change is couched in terms of whether selection factors (e.g., neuropsychological deficits) or socialization factors (e.g., marriage) are more important in determining individual trajectories of crime. Such debate has led to an overexaggeration of the differences between these positions. While this discussion may have been necessary for the emerging life-course perspective, it is now superseded by the recognition that there are both continuity and change in the patterns of crime and that both selection and socialization are important components of such patterns. To advance our understanding of the life-course perspective, the first step is to rephrase the conceptual question from 'Whether there is more stability or change in crimes?' to 'Under what conditions do people continue on their criminal or noncriminal trajectory and under what conditions are there changes in the initial pattern?'

Relatedly, we need to identify similarities across approaches and the conceptualizations contained in different perspectives, as well as explore consistencies in findings across theoretically directed research. David Farrington (2005) has paved the way for these efforts by requesting scholars representing major life-course perspectives address how their theories answer his proposed set of 24 questions concerning issues such as the onset, duration, desistence, and the scope of the theory. Farrington further provides a summary chapter that could be considered a template for identifying the overlap in life-course theories. The next step is to examine the findings on the shared propositions.

Much of the examination of factors that affect changes in crime across the life course has focused on mediating processes. Essentially this approach considers the sequential causal processes that lead to continuity or change in criminal behavior. This, of course, is an essential approach if we are to understand the life course of criminal behavior. However, predicated on the risk and protective factor approach, we are increasingly beginning to see analyses that focus on moderating factors (Krohn et al., 2014; Lizotte et al., 2013). Moderating factors are those that interact with causal variables to either reduce or enhance covariates' impact on criminal behaviors. One potentially valuable contribution of this approach is its focus on factors that could be manipulated to reduce the probability of continuing criminality for those most at risk.

Also, although many life-course theories recognize that genetic factors play a role in accounting for the trajectory of crime, the specifics of that role and relative importance have not been fully explored. In part, this is because criminologists have just begun to seriously consider the role of genetics in their theoretical models. One reason for this is the lack of longitudinal data sets that include molecular genetic data. Fortunately, this is changing as collection of these types of data is becoming more frequent. Shanahan and Hofer (2005) suggest that the gene–environment interaction may manifest in two distinct ways. The most common way this interaction is conceptualized is with the environment playing a moderating role in the relationship between genetic factors and crime. That is, a positive social environment will impact individuals' propensity for crime. Such propensities for crime may be genetically coded. Alternatively, genetic factors may act as a trigger, enhancing the problematic effects of stressful life conditions. Krohn et al. (2013) discuss how contextual triggers may operate in the explanation of the late-bloomer group found in some studies (e.g., see Bushway et al., 2003). Future data collection efforts increasingly need to include collection of molecular genetic data, while theoretical perspectives need to provide insight into the role genetic factors may play in the crime over the life course.

Methodologically, we continue to see the development of analytical tools allowing for the examination of the intra-individual change. One advancement in trajectory modeling that shows promise for examining the relationship among different trajectories is dual trajectory modeling. Dual trajectory modeling allows for two separate outcomes to be modeled via repeated measures over time (Nagin, 2005; Nagin and Odgers, 2010b). Dual trajectory modeling has gained traction not only due to its ability to model co-occurring comorbid outcomes, but also due to the straightforwardness and explanatory power of resulting statistical output (Nagin and Odgers, 2010b). Such output relays information about the unique trajectory groups for both measures: probabilities of group memberships for each estimated trajectory group as well as probabilities connecting trajectory group memberships across outcomes (Nagin, 2005; Nagin and Odgers, 2010b). It is these probabilities relating group memberships across outcomes that have distinguished dual trajectory modeling from other longitudinal methods, with further analyses allowing for examination of variations according to individual-level factors (Nagin and Odgers, 2010b).

In his 2011 presidential address to the American Society of Criminology, Frank Cullen stated, "life-course criminology (LCC) now is criminology" (Cullen, 2011: p. 310). He further noted the current limited utility of what he characterized as adolescence-limited criminology. Indeed, he called for continuing emergence and further development of the life-course paradigm. This article provided an overview of the general life-course approach, reviewed four of the prominent life-course theories, and examined alternative analytical tools for examining crime, and its causes and consequences over the life course.

Abstract

Life course epidemiology examines biological, behavioral, and social pathways that link exposures during gestation, childhood, adolescence, and adult life, and across generations, to influence health and health inequalities in later life. This article traces the origins of the field from its focus on early life factors and adult chronic diseases to a wider investigation of how the trajectory of exposures can act across life to influence disease etiology. It describes how simple life course models are applied to elaborate the independent, cumulative, and interactive effects of exposures. It concludes with recent developments and future directions for life course studies.

Introduction

With the aging demographic profile of many countries, research interest has increasingly shifted toward understanding disease etiology – especially for chronic diseases – and the long-term effects of health behaviors and lifestyle from a whole life perspective. Recent decades have seen the corresponding emergence of life course epidemiology as a coherent discipline within the health sciences. Life course epidemiology can be defined as the study of the long-term effects on adult health and health-related outcomes of biological (including genetic), environmental and social exposures during gestation, childhood, adolescence, earlier in adult life, and across generations (Kuh et al., 2003). This inherently multidisciplinary approach emphasizes the role of timing of exposures and understanding how both risk and protective factors act independently, cumulatively, and interactively across life. The overarching aim of the life course approach is to produce findings that not only can provide insights on the underlying biological, behavioral, or psychosocial pathways operating from the earliest stages of life, but also have implications for public health policy in terms of the optimal timing and targeting of preventive health strategies throughout life.

Historical Background

The core notions of life course epidemiology, regarding the potential of exposures at various life stages – especially early life – for latent and long-term consequences on health, have deep historical origins (Kuh et al., 2003). Yet it was in the nineteenth century, with the burgeoning growth of industrial cities, that we saw a growing awareness of overcrowding, poor sanitary conditions, pollution, and a host of other public health challenges. By the early twentieth century, the perceived decline in the fitness and vitality of the general population was placed at the forefront of the public health debate (Kuh et al., 2003). New maternal and infant welfare services were being funded, which sparked debate over whether fitness was primarily genetic (in which case genetically unfit infants would be kept alive by these services, potentially leading to a degeneration in the population's overall health) or could be encouraged and shaped by early environments and 'maternal efficiency' (which would ultimately improve national fitness) (Pearson, 1912; Paton and Findlay, 1926). While this provides an early example of a life course approach framing the discourse of population health at the time, epidemiological evidence to support either of the propositions was limited (Kuh and Davey Smith, 2004).

In the subsequent decades, interest shifted away from early life influences as postwar cohort studies of middle-aged men focused on adult chronic diseases and identified their more proximal biological risk factors, such as high blood pressure (Kuh and Davey Smith, 2004; Ben-Shlomo et al., 2013). As a result, a life course perspective was apparent only sporadically in epidemiological research. For example, in 1934, Kermack, McKendrick, and McKinlay analyzed British mortality rates from 1845 until the 1930s, and described what are now termed 'birth cohort effects' (Kermack et al., 2001; Kuh et al., 2003). They observed that "the actual calendar year is of relatively little importance in determining the improvement in the specific death-rates" (Kermack et al., 2001: p. 679). Instead they identified that a key determinant was the birth year of the generation or group of individuals under consideration. Exemplifying their life course perspective, the paper concluded that "the important factor from the point of view of the health of the individual during his whole life is his environment up to the age of say 15 years" (Kermack et al., 2001: p. 683). Furthermore, in 1941 Ciocco et al. reported a comparison of the physical examinations of school children with their acceptance for or rejection from military duty 15 years later, based on another physical examination (Ciocco et al., 1941). They found that men who were rejected showed signs of physical infirmity in childhood, with the authors emphasizing in their conclusion that disease onset can be triggered by the aggregate effects of many conditions and/or incidents that occur as early as infancy (Kuh et al., 2003).

Research that would today be considered under the umbrella of life course epidemiology gathered momentum in the 1970s, with for instance work by Forsdahl linking county infant mortality rates to coronary heart disease in later life (Forsdahl, 1977). Forsdahl suggested that poverty in childhood and adolescence followed by later life prosperity might explain the variability in observed mortality from cardiovascular diseases

seen in Norwegian counties. This idea was subsequently popularized and expanded by a group of researchers, under the leadership of David Barker, who concentrated on the prenatal environment and fetal development. The Barker group proposed that the cause of many chronic diseases could be traced back to a critical period in embryological development, during which time the fetus is subject to the influence of maternal nutrition during pregnancy and prepregnancy – a process referred to as 'fetal programming' (Barker, 1998). This body of work, known initially as the 'Barker' hypothesis, stood in contrast to the popular research approach of the time on the impact of adult behaviors. In this somewhat polarized context, a multidisciplinary group of epidemiologists and social scientists from the United Kingdom coined the term 'life course epidemiology,' which instead offered a conceptual framework that could encompass both approaches. The programming hypothesis itself eventually evolved into a more generalized developmental model that extended into the postnatal and childhood period (Gluckman and Hanson, 2004).

The modern revival of life course epidemiology was also ushered in by the progressive establishment of population-based birth cohort studies (Power et al., 2013) and the imaginative and opportunistic use of historical records enabling one to construct a retrospective cohort study. One of the earliest studies to be established was the Medical Research Council National Survey of Health and Development, otherwise known as the 1946 British birth cohort study (Kuh et al., 2011). Originally, this study had been set up to investigate declining fertility, but over time it was extended and strengthened with repeated measures in regular surveys, combined with clinic-based data collection and biological samples. The duration of birth cohort and other life course studies with long-term follow-up also posed unique methodological challenges, such as the retention of cohort members over decades, and implementing robust and consistent survey methods (Pickles et al., 2007; Hardy et al., 2014). As the array of cohort studies matured, however, the wealth of longitudinal data available provided increasing empirical evidence for a multiplicity of links between both the prenatal and postnatal environment and developmental characteristics that influenced adult health, function, disease, and aging. With this catalyst, life course epidemiology began to evolve as a coherent research discipline that could usefully engage with divergent fields including chronic disease epidemiology, developmental biology, epigenetics, neurodevelopment, human development, and social demography (Halfon et al., 2014). This has been accompanied by the ongoing development of a conceptual and theoretical framework for this multidisciplinary research (Ben-Shlomo and Kuh, 2002; Kuh et al., 2003; Mishra et al., 2009). As a result, life course epidemiology is increasingly recognized in the current research environment for its potential to guide health policy and practice (Kuh, in press), with its particular emphasis on evidence that can support the appropriate timing and targeting of interventions.

Life Course Models

Central to the theoretical foundations of life course epidemiology has been the adoption of a series of simple models that form a conceptual framework for studying exposures and subsequent health outcomes using data from life course studies. A description is provided of each of the life course models – *critical period*, *sensitive periods*, and *accumulation models* plus their variants (Kuh et al., 2003; Ben-Shlomo and Kuh, 2002). In most cases these models have been adapted from other disciplines rather than originating within life course epidemiology, but the distinctive aspect of the approach is their delineation as an ensemble to cover the various types of relationships. Thus the strength lies in providing a framework for hypothesizing a specific causal pathway that can be tested against the available data and for combining individual models to form descriptions of far more complicated processes operating through the lifespan. As will be explained, however, none of this obviates the need for a systematic analysis and testing of models and careful interpretation of their results.

Critical Period Model

As the name suggests, the critical period model (**Figure 1**, top) refers to a limited time window within which an exposure is linked with irreversible changes in developmental mechanisms of biological subsystems – typically during a particularly vulnerable stage in life such as the early stages of development – that have adverse or protective effects for disease outcomes in later life (Ben-Shlomo and Kuh, 2002). The introduction has already mentioned the concept of 'fetal programming,' which is the preeminent example of a critical period model. Outside this critical period, no excess disease risk is associated with the exposure.

Sensitive Period Model

This life course model may be interpreted as an extension of the critical period model, in the sense that the effects of an exposure are no longer just limited to specific time window, but rather the strength of the link between exposure and disease risk attenuates outside a sensitive period (**Figure 1**, bottom). In other words, while an exposure may have an effect on outcomes at various periods in life, there is also a period whereby the exposures are particularly important. Whereas critical period models are primarily associated with disease risk that arises from interruptions to the development of particular biological subsystems, sensitive periods are more common in behavioral development that occurs primarily during childhood to early adulthood (Ben-Shlomo and Kuh, 2002).

Critical Period/Sensitive Periods Model with Later Modification

In practice these basic models are typically expanded to include the possibility that the effects during the critical or sensitive period, such as early life, may be subsequently modified by *other unrelated exposures* in later life, and thereby either enhancing or decreasing the risk of adverse outcomes in later life (**Figure 2**). For instance, extremely low birth weight (<800 g) has been linked with the low level of fitness in early adolescence (Rogers et al., 2005). This relationship can be better understood, however, in terms of the impact of premature birth on the development of the motor system, that is then *modified by* (here increased by) the influence of an inactive

Figure 1 Critical (top) and sensitive period (bottom) life course models.

Figure 2 Critical/Sensitive period model with later modification.

lifestyle, so that it is the interaction of these two factors that forms the association with fitness level in adolescence (Whitfield and Grunau, 2006).

Accumulation Model – Independent Exposures and Direct Effects

Even if not explicitly presented as such, the accumulation model represents one of the most widely applied models and takes a number of variants. For independent exposures it refers to a simple additive model corresponding to the number of different exposures, each contributing an additional effect on the risk of the outcome (Figure 3, top). One of the key questions for debate in applying this and other models concerns whether the exposures can be treated as independent, or potentially as a cluster of exposures that result from another single factor or 'shared risk factor' (Figure 3, bottom). For instance, low socioeconomic position (SEP) can be interpreted as a common cause for a range of potential adverse exposures, since it may be related to living in an area where burglary is far more likely to occur, or to have an occupation with less job security.

Accumulation Model – Duration or Dosage of a Single Exposure

Another form of the accumulation model deals with a single exposure over a period of time, and treats the risk as accumulating according to the length of exposure or the dosage received (Figure 4). For instance, as a hypothetical illustration the health risk associated with living in a polluted environment might be considered as proportional to the number of years spent in that environment and may also include an index for the severity of the pollution. Another example might be the health risks associated with the years spent in a sedentary lifestyle, or those linked with different levels of physical (in) activity over the same time period. This simple approach is useful, as often there is only limited information about the exposure, but can also be potentially misleading without careful consideration of the potential mechanisms involved. The issue is discussed in more detail in section on health behaviors and life course trajectories below, using an example of the risks associated with smoking.

Accumulation Model – Correlated Exposures or the Chain of Risk Model

In setting out an accumulation model, the notion of independent exposures needs to be carefully examined. Often exposures are not independent but correlated as a series of related events each affecting the likelihood of the next. There are two versions particularly worth noting: the first exposure may have both an independent effect and an influence that sets an individual on a particular trajectory (Figure 5, top). An example of this scenario is the relationship between smoking and coronary thrombosis. Smoking accelerates the process of hardening and narrowing arteries, thus the risk of blood clots is directly increased. A second independent risk factor for clots is an excess of plasma fibrinogen, which is significantly decreased by exercise (Imhof and Koenig, 2001). However, smoking may

Figure 3 Accumulation life course models with independent exposures (top) and exposures with 'shared risk factors' (bottom), such as socioeconomic position.

Figure 4 Accumulation life course models with same exposure and where the effect increases with the duration or the dosage of the exposure.

Figure 5 Accumulation life course models for independent exposures and correlated effects (top) and correlated exposures (bottom) that form a chain of risk, sometimes ending with a 'trigger exposure' (exposure C) without which the effect on the outcome would not occur.

reduce one's aerobic capacity due to respiratory symptoms, which might decrease exercise behavior and therefore levels of plasma fibrinogen are increased. Both smoking and a lack of exercise independently increase the risk of coronary thrombosis, but smoking also decreases exercise behavior.

The second scenario is sometimes referred to as a 'chain of risk' where the series of earlier events creates a situation or condition that has a predisposition for an adverse outcome to occur, but it is the final exposure that is required for an increased risk of the outcome to occur. The latter scenario is referred to as a 'chain of risk with a trigger' (Figure 5, bottom).

Life Course Models in Practice

Each of these basic life course models can be combined to form a broader set of hypotheses for the causal pathways operating in a particular group. Indeed, given the multiplicity of possible and related exposures that can occur through the life course, it is unlikely to be the case that a single simple model will suffice. Examples of augmented models have already been given, such as the use of modifying factors applied to critical and sensitive models. One of the simplest examples that combine models is where the basic accumulation model is overlaid with the chain of risk model, i.e., where correlated exposures have both direct and indirect effects on the outcome.

If the same exposure is considered, such as SEP of an individual for a series of time periods through life, then the basic critical period, sensitive period, and accumulation models can be formally interpreted as special cases of a more general model. So rather than being qualitatively different, the defining characteristics of the models is described by the constraints applied to weightings for the relationship between the exposure and outcome. (This can be seen visually if Figures 1 and 2 are reexamined, with attention paid to the thickness of each arrow linking exposure to outcome.) Thus for the critical period the weighting is such that the effect of an exposure is derived from one period and exposures at other periods have no contribution, whereas for the accumulation model the strength of the associations are constrained to being the same for each period. The sensitive period model represents the most unconstrained form, since it allows the association to vary from one period to another.

Last, the advantage of these models lies in the way they encourage the consideration of exposures, even at the conceptual level, in terms of *a trajectory* or pathway through life and even across generations. Rather than just a health outcome in later life, there is often a related trajectory for metric of health, such as physical capability, through life. From infancy, through childhood and early adulthood, there may be a series of stages of rapid development as marked by, for instance, aspects of physical capability like grip strength, that typically lead to a peak in adulthood, and followed by a decline in midlife and beyond (Cooper et al., 2014). At each time period exposures such as diet and physical activity, may play a different role in contributing to growth and hence to the peak of physical capability or slowing the rate of its decline over subsequent decades. Furthermore, the direction of any association should be examined rather than assumed; for instance a decline in physical capability may result in a decline in the quality of diet (by it being more difficult to shop for fresh foods), leading to further adverse outcomes in later life. If there are sufficient repeated measures, one of the advantages of life course studies lies in providing insights on causal mechanisms, where data can be evaluated before and after an exposure or health event. Although far from unqualified evidence for inferring causality, findings can nevertheless contribute to either support or refute specific causal pathways.

Health Behaviors and Life Course Trajectories

This ensemble of life course models provides a formal approach for setting out to identify specific mechanisms operating at different time periods in life. Combining models also permits the progressive construction of a more comprehensive model for the effect of exposures across the life course on health outcomes. To achieve this in practice, however, it is important to understand some of the challenges involved in unraveling the different life course models and the role of trajectories of factors.

Without an understanding of the trajectories of exposure, the relationship between exposures at one time point to another can easily result in a potentially misleading interpretation of findings. To illustrate, take a simple cumulative model for a hypothetical example of the trajectory of smoking among women (Ben-Shlomo et al., 2013). Suppose an initial analysis of the data identifies that the length of duration with smoking behavior is associated with an increase in the breast cancer risk (Figure 4). Rather than just duration of the smoking behavior, we might then quantify the smoking exposure in terms of the number of pack-years (that is the number of packs of cigarettes smoked per day multiplied by the number of years of smoking). If the findings again showed a 'dose–response' effect, this might be taken as a clear evidence for a biological mechanism that incorporated a steady accumulation of damage to parts of the breast tissue and hence corresponding increased risk of the disease. In policy terms such evidence might suggest the use of strategies that aim to reduce smoking at any time through life. In a naive interpretation, the evidence would not suggest to priorities targeting of health measures at any particular time point.

Now suppose in further analysis we were to compare the subgroup of women with 20–30 pack-years, but who started smoking in puberty and found their risk was higher than those with the same pack-years but who commenced their smoking behavior later in life (Figure 6). Such findings would suggest a sensitive period model and a possible biological mechanism whereby tobacco exposure during puberty – a time of rapidly dividing breast tissue – presents an additional cancer risk. At least one study has found that initiation of smoking in puberty may be related to a greater risk of breast cancer after taking smoking duration into account (Band et al., 2002). Another perspective is to consider the trajectory of smoking behavior: in a cohort study that investigated the relationship of timing of when smoking behavior commenced among both men and women with the number of pack years over the lifespan, it was found that those who started smoking by the age of 16 were at increased risk of becoming a lifelong smoker (Clennell et al., 2008). In contrast with the interpretation from findings relying on the simple accumulation model above, both of these

Figure 6 Exposure of the same length, but with different effects on the outcome according to when the exposure commenced.

results from additional analysis would strongly support preventive health policies that prioritized discouraging the commencement and reduction of smoking among very young women.

Socioeconomic Mobility and Life Course Model Selection

One of the main research areas of social epidemiology concerns the impact of SEP over the life course – typically signified by education, occupation, or income level. The conventional approach has been to assume an accumulation model, where the effects in later life are proportional to the time spent in a particular SEP category, and with evidence linking low SEP with a swathe of adverse health outcomes (Marmot and Bell, 2012). Further to this is the investigation of social mobility, which occurs when an individual moves from a lower to a higher SEP, or vice versa – though the latter is less often the case. Social mobility can be described as intragenerational, when an individual moves between SEP within a lifetime, or more typically as intergenerational, whereby SEP changes across generations (e.g., from parental SEP during the participant's childhood to the participant's adult SEP).

Social mobility represents an area of considerable interest from a sociological and policy perspective, since it can act as a marker of significant social change, such as improved access to higher qualifications. Yet the interpretation of the effects of SEP and social mobility requires careful consideration both in terms of interpreting the trajectory involved, including across generations, comparison between age cohorts, and the hypothesized mechanism at work. For instance, higher education levels in a young cohort may just reflect broader secular change rather than an improvement in social mobility, per se. Thus secondary education in a young cohort may not confer the same social advantage that it had in previous generations and therefore would not necessarily be expected to be associated with the same health benefits. Identifying SEP and hence social mobility for different population sectors can also be problematic, such as women in older cohorts when work force participation was lower (and then resorting to using data on the SEP of the spouse).

Another aspect to consider is *social causation*, which highlights the pathways in which SEP affects health. For instance, low SEP is linked with an inadequate diet which could be the factor leading to poor health. Similarly *social selection* refers to the possibility of reverse causation, where poor health may lead to low SEP (by for instance limiting the occupation level of the individual). Last, data on SEP through life may cover unequal time periods – sometimes only two data points, with one in childhood and one in adulthood – and hence correspond to different lengths of exposure. This would not be captured in an index used for a simple accumulation model that just scored SEP across life according to the number of data points in a particular level.

Hallqvist et al. (2004) raised the fundamental question of the appropriateness of assuming a priori that SEP should be treated according to the accumulation model. He concluded, however, that unraveling the eight trajectories for SEP that corresponded to the different life course models – critical period, sensitive period, and accumulation model, was intractable. In two subsequent papers, Mishra et al. (2009, 2013) set out an alternative formal approach that overcomes the difficulties by framing each of the life course models as special cases of the more general or *full model*, and differing only by the weighting given to the SEP measured at each time period (and their interaction terms). Thus the critical period model gives full weighting to just one time period, whereas the accumulation model sets equal weights to each time period, as was outlined in the previous section. Essentially each model can then be tested statistically against the full model, to see which provides the best fit. If the basic life course model differs significantly (in statistical terms) from the associations identified using the full model, then introducing the constraints of the basic model has lost information that is encapsulated in the full model. If there is no statistical difference, then the basic life course model being tested captures the relationships as well as (again, in statistical terms) the full model.

These brief examples serve to illustrate how life course models on the one hand provide a way of articulating potential mechanisms or for providing evidence to support specific policy options, such as interventions in childhood or early adulthood compared with other times in life. But on the other, without thoughtful consideration of the appropriate research hypotheses and systematic approach to their analysis, their use as evidence for the support for a specific mechanism or of one policy strategy over another would not be justified. In summary, proceed with due caution.

Current Challenges and Future Directions

We have presented life course epidemiology as an approach that aims to move beyond simple associations of risk factors with health outcomes – findings that have been the historical mainstay of case control and cohort studies – to provide instead a framework for a far more overarching approach and synthesis of ideas for understanding human health.

For example, Halfon et al. (2014) have proposed a Life Course Health Development (LCHD) model where human health develops in response to multiple nested and dynamic genetic, biological, behavioral, social, and economic contexts: during critical and sensitive periods of development, risk and protective factors affect the development of biobehavioral regulatory system; the wider context affects the health at individual and population levels through the impact and timing of biological, cultural, and historic factors (Ben-Shlomo et al., 2013). For epidemiology to address such a complex web and sequence of influences, to examine pathways that optimize health outcomes across the lifespan, life course studies have needed to continue to evolve and expand dramatically.

Multicohort Studies

Age cohort and period effects are an inevitable challenge for many life course studies. For instance, the childhood diet of participants in the 1946 Birth cohort study was subject to the unique restrictions of postwar food rationing in the UK (Wadsworth et al., 2006). Thus findings from that study related to dietary effects on subsequent disease risk may have limited relevance for subsequent generations with entirely different dietary intakes. Though, this 'natural experiment' may aid researchers to control for confounding, as the normal variability in dietary intake by socioeconomic status would have been attenuated given these special circumstances. Additionally, many social conditions and population characteristics have changed even in recent decades. Beyond systematic reviews and meta-analysis, researchers have begun to combine data at the individual level across multiple cohort studies. Specifically, findings from such multicohort studies that demonstrate systematic similarities or differences across cohorts, derived from distinct generations, diverse populations, or cultures, can provide evidence that is more powerful and detailed than those from a single study. For instance, it may be possible to identify the impact of a public policy – such as interventions in early childhood health and education – from the time of its initiation, based on comparison between results from a cohort where this occurred and those from other age cohorts or cohorts from other populations where the policy had not been implemented. Methodological difficulties typically arise with combining data from multicohort studies, such as harmonization of the survey instruments used, which can limit the detail and type of comparisons that can be drawn. Nevertheless an example of an interdisciplinary research collaboration of this type that has been established is the Healthy aging across the life course (HALCyon) research collaboration. This project uses the power of nine UK cohort studies to investigate life course influences on physical and cognitive capability, social and psychological well-being, and underlying biology (www.halcyon.ac.uk; Kuh et al., 2012).

Record Linkage

Often a wealth of information already exists on study participants as part of the administration of health and community services. If the ethical issues are fully addressed – and this issue should be considered paramount – the information from record linkage can represent an immense opportunity to add value to existing cohort studies. For instance, with the participants' permission and appropriate ethics approval, the possibility may exist to link survey data with medical or school records. At the most fundamental level this may allow a cohort study with baseline data in adulthood to be extended as a life course study through the inclusion of sufficient early life data, such as birth weight, anthropometric data to capture childhood growth trajectories and childhood development indices. There is also potential to link with medical and health service use data that would provide further benefits, for instance in quantifying the impact of life events like prolonged unemployment or the impact of early schooling (Baker et al., 2007) on subsequent health service use are potentially invaluable for guiding preventive health strategies. Combined with health survey data from a baseline, these records may reveal evidence for the long-term effects of a widespread treatment in the population, such as the use of antidepressants or hormone replacement therapy. Any such effects may only be implicated in a specific subsample of the population or at a particular time of life, for instance during adolescence. To reiterate, the ethical questions are crucial and need to be addressed, especially the informed consent from participants and the maintenance of their anonymity in any research and findings. Nevertheless protocols are already standard practice in life course studies that can address privacy issues with secure matching of individual records across databases, with researchers only dealing with anonymised data.

Advances in genomic technologies has seen growing interest in the potential for genetic and epigenetic research by gathering biological samples – if they have not previously been done so for other aspects of the study – from existing cohorts for detailed genetic analysis. This means that mature cohort studies that primarily consist of repeat survey data can be reexamined in light of genetic information, such as in the predisposition for certain conditions among individuals, combined with specific environmental exposures that result in a greatly increased risk for that condition becoming manifest.

Family-Based Studies

Family-based studies represent another important emerging direction for life course epidemiology. Rather than focus on just the individual cohort member, family-based studies are designed to collect data on more than one family member (Lawlor and Mishra, 2009). The rational is the familial context which provides multifaceted influences that are fundamental to the developmental trajectory of an individual. Throughout childhood and into adolescence, parents and siblings bear strong influence on one's social and psychological life experience. Furthermore, family-based designs provide a unique opportunity for disentangling genetic, environmental, and social factors, opening up research questions that go beyond simple associations into multilevel analyses. For instance with data on siblings, comparisons within and between different family members can begin to provide evidence as the basis for inferring causality (in conjunction with plausible

biological or other mechanisms) (Lawlor and Mishra, 2009). Family-based studies also present an opportunity for exploring the role of timing of exposures across the life course, since particular family members can have varying effects on one's health at different points through life.

The family-based design is not, however, without methodological challenges (Frisell et al., 2012) due to potential bias from nonshared confounders and greater attenuation of associations with random measurement error. When comparing intergenerational exposures and outcomes or across populations, it is imperative to take into account the changing nature of the family unit and the potential impact on the family environment that such changes might incur. For example, over the last few decades the proportion of working mothers and single-parent families has increased greatly. This might be reflected socioeconomically or have various other social and environmental impacts for an individual (e.g., more time spent in day care). Complex family structures where two single parents and their offspring join to form one household are not uncommon. Family-based studies also pose various other practical and methodological challenges. One example is dealing with proxy responses where one individual provides information on another family member, such as a child responding to questions about their siblings. While in some age groups, the use of proxy responses may be entirely appropriate, such as maternal responses on their infant child, they may also be unreliable, as has been shown in the reporting of disabilities (Todorov and Kirchner, 2000).

Nevertheless, family-based studies represent an essential way forward for life course epidemiology given the increasing evidence for the key role of the nurturant qualities of the environments where children grow up (Maggi et al., 2010). This interest in family-based studies as part of life course epidemiology fits into the broader trend of augmenting existing cohort studies, with direct data collection on family members or through record linkage of registry data. Some recent cohort studies have been specifically designed to address family associations from the outset, such as the Generation Scotland study that comprises of 50 000 individuals within sibling and parent–offspring groups (Smith et al., 2013). The China Children and Families Cohort Study provides another example, with 300 000 families recruited in some cases even prior to conception of the prospective main participant (Brown et al., 2007). New and future family-based studies need to be undertaken by researchers drawing on experience from existing cohort research that have provided methodological rigor and best practice over time. In due course this should permit cross-cohort comparisons at the international level, where the life course approach could be applied to investigate the impact of exposures and disease mechanisms across generations and populations with disparate cultural, socioeconomic, and environmental conditions.

Conclusions

In summary, the life course approach can be seen as having two essential and distinct features of modern epidemiology: it represents a synthesis of ideas from diverse disciplines and a framework for multidisciplinary research, while it also incorporates a set of life course models to provide tools for testing specific hypotheses and causal pathways. This combination of both a broad perspective and detailed focus has facilitated and is reflected in the spectrum of ideas from fetal programming hypothesis to rich theoretical models, such as exemplified by the Life Course Health Development model.

The contribution of life course epidemiology for research translation, to provide insights for causal pathways or to strengthen the evidence base for better targeting and timing of health interventions, is tempered by the need for careful selection of life course models. Methods and guidelines for ensuring that researchers adopt best practice in their analysis and interpretation of findings are at the cusp of recent advances in the field and require much further development.

Yet life course epidemiology is relatively well positioned for the inevitable rise in the use of 'big data' as part of the augmentation of both new family-based studies and existing cohort studies that goes far beyond the traditional use of survey data collection and clinical measures. It provides an established framework that encapsulates an intergenerational perspective and lifespan trajectory, with a way to address the multiplicity of biogenetic and social relationships at work and that lie at the crux of epigenetic research. It is unsurprising, therefore, that in just a few short decades life course epidemiology has emerged as an integral to both current and future directions of public health research.

Abstract

There is an ever-growing body of literature concerned with the life course and life cycle, inspired in part by Philippe Ariès' *Centuries of Childhood* (first English language edition, 1965). The article surveys the central approaches within this historical literature, paying particular attention to the nuances of class, gender, and ethnicity. In addition the article examines the fluidity of age and life course categories prior to the nineteenth century and the tightening of these definitions under the impact of industrialization, nation-state formation, and the rise of positivism in the natural and social sciences. This approach is now being questioned, with recent work restoring a sense of contingency and agency within new interpretative frameworks.

This article will review the changing historical literature on the life course and life cycle from the 1960s to the present. It will begin with the impact of Philippe Ariès' *Centuries of Childhood* (first English language edition, 1965) on the historical study of childhood and then move to the work that has been on youth, middle age, and older age groups since that time. Because the most important developments in the field have occurred in Europe and North America, the piece will necessarily focus on the Western world, using non-Western examples only for comparative purposes. The article will pay attention to the nuances of class, gender, and ethnicity that have been recently introduced into the literature. In addition to reviewing the literature, the article will provide a brief overview of current understandings of the life course from early modern to modern times. It will discuss the fluidity of age and life course categories prior to the nineteenth century as background to understanding the tightening of these definitions under the impact of industrialization, nation-state formation, and the rise of positivism in the natural and social sciences. It will show how in the last 20 years these categories have come to be questioned, and how new understandings of the life course and aging are now emerging in the context of the demographic change, the restructuring the nation-state, and the emergence of new interpretative frameworks. The piece will conclude with a sense that historical studies of the life course and life cycle are moving in a humanistic direction, restoring a sense of contingency and agency that was apparent in the first generation of historical treatments of the subject without entirely displacing more positivist notions.

The history of the life course, of age categories, and of aging is essential to understanding how any society organizes itself over time. The notion of life cycle was first used by social science in the 1930s, but has now been superseded by the more flexible notion of life course. Historians had long been interested in the aging of individuals, but were slower to appreciate the social dimension. Today, however, notions of life course and aging are as essential to historical practice as they are to the social and behavioral sciences.

Foundations of the Field

Representations of the ages of man had previously attracted the interest of historians of art and religion, but it was not until the 1960s that the life course became a focus of social and cultural history. Beginning with Philippe Ariès' *Centuries of Childhood* (1962), there began a veritable avalanche of studies which have explored the history of every dimension of the Western life course from the Greeks to the present. Today there is a substantial body of literature on the history of childhood, youth, old age, and death, focused mainly on Europe and North America, but also touching on the non-Western world.

Ariès was concerned mainly with representations of aging, but his successors were influenced by the social sciences to direct their attention to behavior. The first generation of new work in the 1960s and 1970s was heavily influenced by historical demography, psychology, biology, and quantitative sociology, seeking to define general patterns of historical development and understand the structures and functions of age groups.

Today, the influence of positivist notions of human development are less evident. In the most recent studies of the life course it is the variability and instability of the life course and age categories that have gained the most attention.

Development of the Field

The historical study of the life course began with childhood, moved subsequently to youth, old age, and death, and, most recently, has focused attention on midlife. This sequence is less the effect of research design than historical contingency. The youth movements of the 1960s accounted for the interest in the history of adolescence; the evident importance of older age groups as a consequence of the longevity revolution focused interest on them from the 1970s onwards. Death and dying became important topics in the same period, while the recent work on mid life reflects the uncertainties experienced by adults in recent decades. What began as a field concerned mainly with the middle-class male life course has now become much more sensitive to gender and ethnic differences, yet another reflection of the ways in which the studies in this area reflect contemporary concerns.

The study of childhood has undergone dramatic changes since it was introduced by Ariès. His notion that there was no concept of the child before the early modern period was immediately challenged by medieval and Renaissance

historians who produced linguistic, artistic, and medical evidence of concern with children in their respective periods. The idea that children were subject in premodern times to an indifference bordering on neglect has also been modified in recent decades, so that we now have a much more nuanced view of earlier eras of child rearing and childhood, but one that preserves the essence of Ariès' original insight into the malleability of notions of childhood over the centuries. We have come to understand that practices such as abandonment, which may seem cruel to us, made sense in other social and cultural settings.

Ariès' insight into the mutability of age categories also influenced the first generation of studies of youth. It became clear that in premodern Europe youth was more a function of social context than biological age. Numerical age was less important than work and marital status in defining the boundary between youth and adulthood. It was not until the later nineteenth century that entry and exit into this age category became standardized, and then mainly for middle-class males who constituted the first group to be called 'adolescents.'

It was not until the twentieth century that everyone was seen as being entitled to both a childhood and an adolescence as these were defined by the emerging medical and psychological sciences. As the understanding of childhood and youth became ever more universal and precise, there developed a notion of a normal life course, leading through adulthood to old age. By following the proper rules of aging, individuals could expect to arrive at what Erik Erikson, the major theorist of the linear life course, deemed a coherent understanding of themselves and life more generally. Failure to move through the prescribed stages of life in a timely manner was often portrayed as a cause of personal and social disorder.

By the 1980s, attention had become focused on old age and death. As more and more people began to live longer, healthier, more active lives, many stereotypes of older people began to be challenged. Old age could no longer be equated with poor health, debility, and passivity. These changes contributed to new interest in old age in earlier periods, and a more nuanced view of aging and 'retirement' in the past. It turned out that the modern period has no monopoly on notions of good aging or, for that matter, of the good death.

Even adulthood, that part of the life course that had previously been neglected by historians because it seemed so universal and unproblematic, has come in for its share of attention. Awareness of midlife crises, first among men and later among women, prompted a number of recent studies focused on the changing nature of adulthood over time. Studies of fatherhood and motherhood demonstrate just how historically variable this dimension of the life course has also been, and how changing definitions of masculinity and femininity, and of sexual orientation, have affected notions of adulthood over time.

Premodern and Modern Life Courses

Historical work from 1960 to 2000 has complicated our understanding of the life course and aging in the present as well as in the past. It is now generally agreed that prior to the modern era, age boundaries were more fluid and the life course less rigidly segmented. The identity of premodern peoples was determined less by how old they were numerically than by the status or place they occupied in the social order. In a society where heading a household conferred adulthood regardless of age, a property-less man or woman would remain a 'boy' or 'girl' all his or her life. Schooling was not age graded and there was no set age of retirement.

The nature of the agricultural economy, the absence of centralized institutions, and high levels of mortality and fertility all contributed to this condition. So too did a prescientific culture, which had no notion of universal quantifiable laws of nature, but was prepared to accept sudden, nonlinear qualitative change as quite normal.

All this changed in the course of the nineteenth century. For the first time numerical age came to define status for a growing part of the population. In a process that Martin Kohli has called 'chronologization,' age became the criterion for schooling, entry into work, and military service. By the end of the century, it was also associated with entitlements such as retirement and welfare benefits.

Chronologization proceeded fastest among urban populations, affecting middle-class men first, but by the early twentieth century it was shaping the lives of a majority of the European and North American populations. Not only was aging standardized, but it was normalized, producing an acute sense of being too old or too young for certain categories of activities. The life course was organized into a linear sequence consisting of childhood/youth, adulthood, and old age, each with its appropriately gendered roles and expectations. By the mid-twentieth century, norms of successful aging held sway throughout Western society and were being exported to the non-Western world as integral to what it meant to be modern.

In retrospect, we can see that chronologization was the product of an urban industrialized society concerned to maximize productivity through the rationalization of time, including age. The newly developed nation-state was equally interested in maximizing the resources of its citizens by organizing them into age cohorts. These efforts were reinforced by the new biological, medical, and psychological sciences, which took over the responsibility for assigning meaning to age and aging from religion. By the beginning of the twentieth century, each age had its own body of expertise. Childhood was now covered by the newly invented field of pediatrics; adolescent psychology was recognized; and a new discipline of gerontology would soon develop. In our own time, death has become yet another area of expertise, thanatology.

The process of chronologization reached its apogee in the post-World War II period, but by the 1980s some were foreseeing the arrival of the 'age-irrelevant society.' Since 1980 there has been a noticeable dechronologization of the Western life course. Not only has numerical age ceased to be such a powerful determinant of status, but the boundaries between ages have blurred and new age categories such as the 'young–old' or what Peter Laslett called the 'Third Age.'

The timing and sequencing of the life course have become less uniform and normative. The ages of entry into and leaving work and schooling show greater variation. The same is true of marriage and parenting. Given new reproductive technologies, the biological clock is no longer as determinative of women's life course. There is no longer consensus on what constitutes

a child, a youth, or an old person. Adulthood, previously that part of the life course that could be taken for granted, has also become problematic.

All this has led to a reconsideration of the linearity of the life course. In the late twentieth century, the institutions that once enforced age norms no longer did so. Schools, employers, and the state all now acknowledge, even encourage, flexibility with respect to age. More concerned with consumption than with production, Western industrial society has encouraged both younger and older age groups to enter into roles in the marketplace previously reserved for adults. Children and the youth have become major consumers, while older persons are encouraged to lead active lives in the consumer society.

The nation-state has also relaxed its age criteria. Its high-tech armies are no longer composed exclusively of young men, but now include not only women but a much wider range of age groups. Today boundaries between age groups blur. The legal distinctions between childhood and adulthood have become less clear. Legal ages of drinking, driving, and voting have all been revised in recent decades.

While most people still maintain some normative notion of the life course, this gets less reinforcement than it once did from the medical and behavioral sciences. Recent studies have challenged the predictive power of numerical age in everything from learning capacity to physical fitness. It is no longer clear that life follows a uniform, predictable sequence. Gender differences and variation by class and ethnicity have complicated the contemporary picture of aging to the point that generalizations become increasingly suspect.

Today, age is seen as more subjective, more contingent. We seem to be returning to a situation similar to that which existed before the process of chronologization began. But now it is not one's status that determine's one's age, but one's own effort. We are told that how we age is up to us, dependent on how we eat, exercise, and medicate ourselves. Notions of successful aging and the good death were present in earlier periods, but were largely defined by religion. Today, religion competes with the prescriptions of science and medicine. As recent studies show, factors of class, gender, generation, and ethnicity still have a powerful effect on the way we think about age. However subjective age categories have become they do not exist outside history or culture.

Current State of the Field and Future Directions of Research

Current interest in the history of the life course reflects contemporary uncertainty about aging and the desire to know more about its contingent nature. The history of the life course and aging is no longer so influenced by the behavioral sciences as it once was, while, at the same time, psychologists and sociologists have become more aware of the historicity of their subject. Psychologists now question the notion of a linear life course and the assumption of universal laws of development that underlay it. It is now generally acknowledged that gender, class, race, and cultural background have enormous effect on the life course and life chances.

The relationship between history and the behavioral sciences has been profoundly altered. There is now much greater appreciation of the variability not only of conceptions of age, but of age relations themselves. Aging has ceased to be seen as some invariable law of nature, to be discovered and obeyed. It is no longer a problem to be formulaically solved, but a challenge that confronts every generation and to which there is no one answer, only an ongoing dialogue with ourselves and others about the meaning of age.

No period in history has ever achieved agreement on the question of when life begins and ends, or how the life span should be divided or sequenced. Furthermore, our conceptions of life are not limited to the actual life span. We have the capacity to imagine life before birth and after death, and conceptions like the fetus as 'unborn child' or notions of life after death have very powerful effects on the way we lead our lives.

Over time the perceived number of ages of man has varied enormously. Some cultures have assigned the highest value to the oldest ages; others have valorized childhood or youth over age. The so-called 'prime of life' has been equally variable over time and space. Even within a single society in a given period, people have thought about the life course in very different ways. Religion, which has traditionally been the source of ideas about age and aging, has always been a point of division. Catholics traditionally assigned meaning to particular moments in life, such as the deathbed, while Protestantism insisted that every moment was equally significant in the eyes of God.

Today, intrareligious battles over the meaning of the life course pale in comparison with the struggles between religion and science over the definition of the beginning and ending of life.

Different class groups have also been at odds when thinking about the life course. And there are obvious differences in the ways that different ethnic groups think about age and aging. Gender is also a source of variation. The notion of the linear life course has been closely associated with a certain kind of middle-class masculinity, which places great value on the development of a career. Until recently, few women have had access to careers, their lives having been more contingent on family responsibilities. They have tended to have a more flexible notion of the life course and to be more adaptable than men. In the late twentieth century, when so many people lived beyond all previous societal expectations, this kind of flexibility proved to be a great asset.

It is clear from recent research that the life course is as much the product of culture as of biology. Life is not so much a script we follow, as one we as individuals and as societies write as we go along. In premodern times that script was a religious one. In the nineteenth century, the natural and behavioral sciences took over its authorship, producing a grand narrative of the life course sufficiently consistent with the requirements that the dominant economic and political institutions endowed it with until the fourth quarter of the twentieth century.

Today, the traditional naturalistic grand narrative no longer suffices. The global economy demands flexibility; the nation-state ceases to police age boundaries and moves to divest itself of the entitlements (public schooling, mandatory retirement, social security) that were once associated with age. Individuals are encouraged to become more flexible and

self-reliant, charged with the responsibility not only for defining but narrating their own life courses. This is reflected in the explosion of personal memoirs and family histories in the last few decades. In the absence of grand narratives of the life course, everyone seems bent on telling his or her own story.

This new development represents both a freedom and a burden to individuals, and a challenge to experts in the area of life course studies. It requires a new sensitivity to what people are telling us about their lives, new methods that go beyond the old quantitative measures of age to assess subjective experience of aging. It also calls for new theories of aging that take account of the interaction of cultural and biological factors. Historians as well as social scientists now acknowledge that we inhabit not only a physical world but also a symbolic world, and that it is the interplay between the two that determines the history as well as the sociology of the life course and aging.

Historians as well as behavioral scientists have begun to acknowledge that the sources of data they have traditionally relied on to measure aging, mainly physical and behavioral data, tells us only part of what we need to know. They are beginning to explore further the stories that people have told themselves about the aging process and how different subcultures have imagined the life course. For it is through these that we grasp the ways in which people not only think about age but think with age, and how the meanings that are constructed through and around the life course affect the way we live. For we not only live with certain historically defined notions of life course and aging, but live by them. These constitute the source of the meaning as well as the structure of any social system.

Historical studies of the life course and aging are beginning to turn to those humanistic disciplines such as literature and art history traditionally devoted to close analysis of language, narrative, and images. This does not mean that they are discarding the alliances with the behavioral and social sciences that have been so productive to this point, but rather that all the disciplines concerned with the life course and aging have become more aware of the need to examine their epistemological and ontological assumptions.

Abstract

The study of individual lives has long been a major focus of social science, but approaches to this field of study have evolved considerably over the last century. Increasingly, the pathways that individuals take through life have been contextualized within the broader social, economic, and cultural changes of society as well as long-term population change and shorter-term historical events. The concept of the life course captures this contextualized nature of human lives, and life course theory presents an orienting frame for studying lives this way. This article gives a basic overview of the life course as both concept and theoretical paradigm.

Studying Individual Lives

As a concept, the life course refers to the socially structured sequences of events and roles that organize and direct the life trajectories of individuals. The term life course also refers to a general theoretical orientation, a framework for studying individual lives by facilitating the questions that need to be asked and guiding how the answers to these questions can be pursued. This perspective, life course theory, emphasizes the dynamic mutual influences between the age-graded sequences of the life course and unfolding patterns of development, adaptation, and experience within economic, social, cultural, and historical contexts. This theory fuses together the insights and approaches of multiple disciplines – especially sociology, psychology, history, and demography – and draws on a data sources that are longitudinal and multi-level to link the individual and society in concrete ways.

Just as human lives are historically embedded, so too is the scientific study of human lives. The clear momentous effects of major events of the early twentieth century (e.g., depressions and wars) on adults and children proved to be highly influential to the formulation and development of life course theory, aided by the emergence of new longitudinal panel studies. As the latter half of the twentieth century played out, population change (e.g., the increasingly old age structure of American society, rising immigration, and differential fertility by race and social class) emphasized the need to examine the full span of life as well as the substantial diversity in lives. Contemporary social change, such as the global economic restructuring that has reshaped work, education, and family roles and opportunities as well as the loosening of norms about gender and sexuality, have injected new ways of thinking about role sequences, age-related expectations of behavior, and the wide array of contexts that shape the basic direction of life trajectories. Over time, research and theory on the life course has grown more refined to capture the increasing complexity of lives in the modern world.

To give an overview of the life course as both a concept and theory, this article explains its basic components (e.g., trajectory, transition, and turning point), including a discussion on related terms that are often used interchangeably despite their distinct meanings (e.g., life span, life cycle, and life history). After describing the emergence of life course theory and its influence on research on the life course, this article turns to five fundamental principles of the theory – lifelong development, timing, linked lives, human agency, and historical time and place – before closing with new directions of research that can work from and build on these principles on the way forward.

Basic Concepts

As already noted, the life course is a dynamic sequence of age-graded events and social roles that are embedded in an evolving social structure. This concept is the centerpiece of life course theory, which is concerned with the trajectories of individuals – the pathways that they take through time – and how these trajectories reflect and reshape the social expectations, norms, and values about individual action and behavior (Elder and Shanahan, 2006). Trajectories play out within specific domains of life, so that an individual life can be thought of as a tapestry of trajectories of education, work, marriage, civic engagement, and other experiences representing engagement with major societal institutions as well as psychological and behavioral trajectories, such as cognitive functioning, mental health, and criminality. Trajectories within a specific domain are often referred to as 'careers,' such as the educational careers of children traversing the K-12 elementary system or the criminal careers of adult men going back to their adolescence.

Embedded within long-term trajectories are transitions, which are the concrete short-term changes in role, status, state, or setting that give trajectories their distinctive form and meaning. Frequently discussed examples of transitions include leaving home, entering the labor force, marrying, and retiring but also more biological events such as going through puberty or entering menopause. Transitions can be quite complex, and many can be internally divided into multiple micro-transitions that link together to produce a major life change. For example, an individual marital trajectory might involve several transitions involving multiple partners, as an individual breaks up with a partner, spends time alone, and re-partners with someone anew. At the same time, the single breakup within

that individual marital trajectory might be decomposed into periods of alienation, separation, divorce, and recovery (Cherlin, 2009).

Importantly, transitional periods are when a major change in life trajectories (i.e., a redirection of individual pathways) are most likely to occur. When such changes are anchored in transitions, those transitions can be labeled as turning points in the life course. Trajectories of crime offer several insights into how turning points work. One of the strongest predictors of whether long-time criminals desist from their criminal activity is whether they marry – a mechanism of social control with power to break antisocial associations (Warr, 2002). As for turning points outside the personal realm, unexpected historical events can also sharply alter criminal trajectories. In one striking example, the recidivism rates of new parolees in New Orleans diverged sharply before and after Hurricane Katrina because that cataclysmic storm powerfully disrupted criminal networks (Kirk, 2009). Moving to another domain, the schooling careers of US children – which can be thought of as long sequences of curricular statuses – illustrate how more institutional transitions can be turning points in individual trajectories. For most youth, the transition from middle school into high school is experienced negatively (e.g., as a source of stress and disruption) or neutrally, but this transition can be quite positive for students who had done poorly socially or academically in their middle schools, as long as they enter their new high schools with few of their middle school classmates. In this way, a quirk of district-directed feeder patterns can allow some struggling youth to turn their educational careers around (Langenkamp, 2010).

These basic concepts can be applied to different levels of the life course; in other words, the normative life course of a society or the specific life course of an individual in that society. First, institutionalized pathways may be established on the population level by laws and social policies of the state or firm, such as when the presence or absence of family leave policies influence how women combine work and parenthood or whether they transition from one role to another. Second, the individual life course is worked out at the micro-level in terms of choices and lines of action, such as when women make decisions about the timing of fertility based on their own expectations about work and current work circumstances. Third, the developmental trajectory of the individual is influenced by biological, cognitive, and other personal characteristics, such as when personality or intellectual traits facilitate or interfere with women's balancing of work and parenting activities (Bianchi, 2000).

For example, school-to-work patterns in industrialized societies involve young adults exiting the educational system, entering the labor force, and then iteratively moving through positions and jobs. These patterns are highly structured by larger social and institutional systems, such as the organization of firms and industries, policies that regulate schools and the labor market, and fluctuations in economic climate. Economic work has demonstrated that young adults who graduate from college during economic downturns have truncated earnings trajectories over subsequent decades because their initial job mismatches mean that they start the cumulative career-building process at a disadvantage (vs if they entered the labor force during another era) and then have to play 'catch up' (Kahn, 2010). On the other side of school-to-work patterns, early disparities in cognitive and academic skills, which reflect both environmental and genetic influences, lead to disadvantages in curricular placements and other schooling positions. These disadvantages compound from year to year and ultimately lead to larger disparities in end-of-school outcomes that then shape future work prospects (Entwisle et al., 2005).

Other concepts are related to the life course, some closely enough so that they are often *used interchangeably with the life course*. Similar to a life trajectory, life cycle describes a sequence of life events from birth to death within any domain, although it more accurately refers to stages of parenthood over the life course – the birth of a first child to the departure of children from the home to the childbearing of the next generation and the transition into grandparenthood. The life cycle is repeated from one generation to the next and links together generations. Similarly, life history typically refers to a lifetime chronology of events and activities as well as social psychological processes that occur within and between them. Life history interview techniques can be retrospective and lead respondents through their own personal histories with a recounting and dating of major transitions, or they can be prospective and focus on the present and look forward to the future (Giele and Elder, 1998). Finally, life span is a term more common in psychology that refers to the temporal frame of study – how much of life is being considered. A life span study extends across a substantial period and links behaviors in at least two stages of life, if not more. As such, life span work stands in contrast to much of the developmental and aging literature, which often focuses on one period or stage at a time. All three of these terms stress the value of studying how individual lives unfold over time and, as such, capture the basic spirit of the life course approach.

The Development of Life Course Theory

The 1960s and 1970s proved to be the seminal years in the emergence of life course ideas. A major source of inspiration in this development was the presence of pioneering longitudinal data collections with children who had grown up decades earlier, samples that had potential for analysis beyond simply following unfolding developmental patterns (see Bruckner and Mayer, 1998). The Oakland Growth Study and Berkeley Guidance Study, which were housed at the University of California–Berkeley, and the Stanford-Terman Study at Stanford University are prominent examples. They had existed for many years and had been studied extensively, but they also had untapped potential, including their long-running span into adulthood and their contiguity to major historical events. As such, they offered new opportunities to study lives as dynamic, socially structured, and historically embedded and to develop a deeper conceptualization than growth-oriented ontogeny.

One foundational advance of this early period was the formulation of life span concepts of development, including plasticity (i.e., the potential for change), agency (i.e., self-direction and control of one's own experiences and settings), and the mutual feedback between individual and context (Lerner et al., 2010). In psychology, these advances led to an emphasis on inter-individual diversity and intra-individual continuity. In sociology, they led to the conceptualization of

some of the core concepts of life course theory and the articulation of processes of cumulative disadvantage and advantage. Life-span thinking on human development occurred initially with little attention to a well-established role-theoretical perspective on human lives, dating back at least to Thomas and Znaniecki's (1918–20) *The Polish Peasant in Europe and America*. Such perspectives provided a way of thinking about socialization, generational succession, and social networks into the 1960s. The central concept at the time was life cycle; it depicted life organization in terms of generational succession through kin relations. Yet, one area in need of further development was timing issues of role entry, exit, and duration that needed to be more explicitly linked to temporality and positioned within historical time. The work of Neugarten (1968) on age norms and age-graded roles facilitated such development. This work documented the variability in life when individuals assumed major social roles and packaged them together. Role timing, sequences, and configurations continue to be influential in the social and behavioral sciences, especially in relation to the evolving transition from adolescence to adulthood in USA and other western countries (Settersten and Ray, 2010), and the decoupling of marriage and parenthood (Edin and Kefalas, 2005).

Another foundational advance during the 1960s and 1970s was the increased understanding of individual experiences in the context of particular historical contexts and events, including Ryder's (1965) conceptualization of cohort as a tool for studying social change. In general, cohort refers to groupings of individuals according to some temporal dimension, such as entry into a system or year of birth. A birth cohort demarcates individuals who experience historical events at the one age from those who experience them at younger or older ages. Cohort effects, therefore, occur when the experience of some historical event differs across cohorts; in other words, according to how old individuals are when it happens. When the Cultural Revolution occurred in China, for example, many adolescents and young adults were 'sent down' to rural areas to be resocialized, but older citizens were not. Being sent down then had lasting effects on the lives of those cohorts that had no real counterpoint in older segments of the population (Zhou and Hou, 1999). Cohorts often differ in norms and values and define themselves in contrast to older and younger cohorts, representing different contexts for coming of age and then aging. For instance, age-period-cohort analyses of substance use have revealed that apparent historical and developmental trends in marijuana use actually reflect the progression of the baby boomer cohorts transitioning into, through, and out of their prime drug-using years. Younger cohorts have turned to other drugs, leading to changes in the overall population distribution of substance use (Miech and Koester, 2012).

These different streams of research and theory were exemplified by the work of Elder on cohorts of children growing up during the Great Depression and traversing adulthood in the context of World War II, work that proved to be seminal to life course theory (see Elder, 1999). Elder began by exploring issues of generational change, socialization, and social roles but soon turned to the analytical and conceptual meaning of age as a means of linking family and individual experience to historical change and identifying age-graded trajectories across the life course. His research explored Ryder's ideas about cohorts by comparing the effects of drastic income loss during the Great Depression on the life experiences of the Oakland cohort members (born 1920–21) with those of a younger Berkeley cohort. As an illustration of cohort effects, the younger boys were more adversely affected by family hardship than the older boys. As an illustration of the value of tracking role sequences and life trajectories, these differences faded in subsequent years as the youth moved through the education and into the labor force, entered military service, and formed families.

From this seminal research, life course theory has continued to be constructed and refined over decades, so that it is now a general framework for studying lives in context that influences research on multiple topics (e.g., education, families, health, and immigration) in multiple disciplines (e.g., sociology, economics, and public health). This theoretical development has both inspired and been influenced by significant advances in methodologies for studying lives dynamically (e.g., growth curve analyses and sequence analysis) and within context (e.g., multilevel modeling and social network studies), the proliferation of long-term longitudinal population studies for public use (e.g., the US Panel Study of Income Dynamics and its numerous European counterparts, such as the Socioeconomic Panel Study in Germany; the US National Longitudinal Study of Youth and the British cohort studies), and the increased emphasis on mixing quantitative and qualitative approaches (Elder et al., 2003).

Principles of Life Course Theory

Life course theory is defined by a set of core principles. The first principle is that *human development is a lifelong process*. In short, individual behavior cannot be fully understood by focusing solely on the specific life stage in question. Where someone is at any one point reflects the legacy of past experience as well as anticipations of the future. For example, overweight youth who become thin adults often have mental health profiles more similar to overweight adults than thin adults, as identities developed in the context of the stigmatization of their weight early in life prove to be difficult to leave behind even when weight has been lost for years (Carr and Jaffe, 2012).

A second principle of life course theory is the importance of *timing*. People and their situations change across the life course, raising the probability that influences also differ by stage of life. At the same time, the meaning and implications of particular life transitions can change with age, with transitions being on or off time and timetables being compressed or slow. Although timing is often illustrated by age-related differences in the experience of role transitions like the entry into grandparenthood or exit from the labor force, biosocial research offers new ways of thinking about timing. For example, genetic influences on problem behavior can switch from being expressed in conduct disorder in childhood to substance use in adolescence and young adulthood as young people move outside the direct control of parents and navigate broader social networks (Dick et al., 2006). As another example, going through puberty earlier than the norm can have negative effects on girls by selecting them into older peer groups and sexualizing them before they are psychologically mature (Mendle et al., 2010).

Finally, the development of socio-emotional areas of the brain temporarily outpaces the development of cognitive capacities in the brain, leading to sensation-seeking and reward-oriented behaviors that often pose physical dangers to young people. The potential impact of peer influences on youth, therefore, depends on how far along they are on this age-related process of brain development (Steinberg, 2008).

Linked lives is the third principle, stressing how the circumstances and experiences of one individual can affect other people to whom they are connected. Although linked lives refers to a wide variety of social and personal relationships, this concept most often is discussed within the context of families. As an illustration, the partnership histories of mothers shapes the behavioral and educational trajectories of their children, with students having more trouble navigating the stratified, cumulative curricula of high schools when their mothers have had much more turnover in their romantic unions. The mechanisms linking lives across generations in this way involve not only the resources that mothers can muster to support their children's education but also their own engagement in parenting (Cavanagh and Fomby, 2012). Going in the other direction, the health and well-being of aging parents can be deeply distressed by the long-term burdens of caring for disabled or unhealthy adult children (Seltzer et al., 2011).

As for the fourth principle, namely *human agency*, the life course is shaped by the choices individuals take and the actions they make, even as the availability of choices and actions is constrained by broader social forces. In educational research, ample evidence suggests that the most important determinant of academic positions in secondary education is the demonstrated ability and performance (e.g., test scores), but also that, even within ability/performance levels, students from more privileged backgrounds manage to obtain more advantaged positions by making more informed and strategic decisions within the general boundaries set by their academic histories (Jackson, 2013). On the other hand, biosocial work suggests that genetic influences are influential determinants of behavior in situations of strong social control (e.g., well-organized communities with dense social ties) but that behavior reflects greater personal agency in situations of low social control (Guo et al., 2008).

All four principles up to this point play out within *historical time and place* – the fifth and final principle. Especially in societies undergoing rapid change, a different birth year exposes individuals to vastly different worlds, with their associated constraints and options. For example, Silbereisen's (2005) work on transitioning to adulthood revealed the powerful influence of reunification of Germany as compared to the years before or after. As another example, pregnant Arab–American women had more negative birth outcomes if they were pregnant in the aftermath of the 9/11 attacks rather than before (Lauderdale, 2006). Some aspects of historical time and place, period effects, are less context-specific but instead encompass influences of social change that are relatively uniform across successive birth cohorts. Divorce is more likely and less stigmatized today than it was decades ago, which alters the experience of divorcing. Similarly, coming out as gay or lesbian is a different experience now than even a few years ago.

Challenges and New Directions

Today, the study of the life course as the link between individuals and society is a prominent field of research activity that connects multiple disciplines, both aided by and encouraging data collection on lives as they unfold within contexts over long periods of time. The development of the field – and of life course theory in particular – is expected to continue, and opportunities for advancing the field are numerous.

First, the task of linking early and later experiences in the life course remains a challenge, even with the explosion of longitudinal data. Studies have traced the persistent effect of early events and experiences to later outcomes, but the chain of linking mechanisms is largely uncharted.

Second, advances in how to capture life experiences, circumstances, and behaviors in more dynamic ways have been significant and similar significant advances in how to link dynamic trajectories across domains (e.g., education, family, and health) are needed. Methodologies such as parallel growth mixture modeling, which produce categories of individuals based on configurations of different trajectories, is an example of how such advances can be made.

Third, biological as well as social events are clearly linked to life patterns, and the biosocial examples mentioned in this article suggest that the interplay of the two is increasingly studied. Such approaches are a growth area in life course research.

Lastly, these future directions are all subsumed within the general need in this field of study for cross-cultural comparisons, both within and between societies. European life course research has led the way with this approach (see Blossfeld, 2009). Such comparisons are the most effective way for considering the social and historical embeddedness of human lives.

Abstract

How do people manage their lives? Is it possible to identify general processes of life management across the entire lifespan? After a brief historical introduction to the relatively new concept of life management, these questions are addressed by discussing three central approaches to investigating life management in developmental psychology. These three complementary approaches are (1) self-regulation models of life management, (2) models focusing on age-related expectations as guidelines for managing one's life across the lifespan, and (3) models stressing the role of personal goals as building blocks for life management. These three approaches are not mutually exclusive but complementary and converge in stressing the importance of motivational processes and goals for life management across the lifespan.

Brief Historical Perspective on the Concept of Life Management

The term life management is not frequently used in the psychological literature. One of the reasons might be that the active role of the individual in managing his or her life has only entered psychological models after the 'cognitive revolution.' In the following section, a brief historical overview of the emergence of the concept of life management is given, concluding with a tentative definition of the term 'life management.'

Emergence of the Recognition of the Active Role of the Individual in Shaping One's Life

To introduce the notion of 'life management' into the description and explanation of human development implies the assumption that people actively contribute to their developmental pathways and are not entirely under the control of external stimuli or biological processes. Although hardly controversial nowadays, it took a revolution – the 'cognitive revolution' – to introduce this notion into psychology in the 1960s that was dominated by behaviorism of the Watsonian or Skinnerian type. The importance of self-regulation for describing and predicting human behavior was stimulated by research by Mischel (1968). Their research has convincingly shown that situational, external stimuli are but one factor influencing behavior and that, when attempting to understand human behavior, it is necessary to take sources of behavior regulation into account that lie within the individual (i.e., self-regulatory processes).

Developmental psychology has long been dominated by the view that development is best described either in terms of biologically determined maturation (i.e., unfolding of a biological program or blueprint) or as the result of a specific learning history in the sense of classic and operant conditioning (Kazdin, 2012). The latter view is exemplified in Watson's famous statement that if one were to give him a dozen babies he could – by arranging the environmental conditions – produce whatever adults one would wish to see (Watson, 1925). Watson also noted that he was overstating the role of the environment but he wanted to juxtapose the introspective approach to psychology focusing on inner states such as feelings and thinking with the behaviorist position. Although the interaction of biological and environmental factors for development has also been stressed early on, for instance by Piaget, the proactive role of the individual in creating his or her development has only been recognized fairly recently (Baum, 2005). In this perspective, development is viewed as the co-constructive interplay of biology, culture/society, and the individual (Heckhausen, 2006). On the one hand, individuals proactively shape their environment and place themselves into certain contexts. On the other hand, individuals react to their environment by continuously adapting and reacting to their physical, cultural, and social environment.

One important way in which individuals play an active role in their development is by choosing, committing to, and pursuing a set of (life-)goals such as wanting to become a teacher or deciding to have a child. The kind of goals a person develops and commits to is, again, embedded in sociocultural, biological, and phylogenetic factors. The less behavior is under control of these factors, the more degrees of freedom a person has to choose what personal goals he or she wants to pursue and how. In other words, the less societal or biological influences structure and determine which, when, and how to pursue goals, the more influential are self-regulatory processes for life management.

An Attempt to Define *'Life Management'*

The term 'life management' is only rarely used in the psychological literature. When searching the currently most comprehensive database for publications in psychology (PsychInfo 11/2000) for 'life management,' only 72 publications are listed for the past century, mostly referring to coping with stress in various life-domains such as work, family, or health. In this context, 'life management' is mostly used more or less synonymously with 'coping.' Taking a developmental perspective, however, a focus on coping appears too narrow. I propose to use the term life management in a broader sense to refer to how

people actively take part in and shape their developmental trajectories across the lifespan.

Central Approaches to Life Management in Developmental Psychology

Currently, there is no unified model of life management in psychology. Instead, there are a number of approaches to life management that can loosely be clustered into three groups: (1) self-regulation models, (2) models focusing on age-related expectations, and (3) models stressing the role of personal goals. Despite their differences, these approaches have in common that they stress motivational, goal-related processes as central processes of life management across the lifespan.

Self-Regulation Theories

In contrast to 'life management,' self-regulation is a popular concept with more than 1300 entries listed for the past decade in the PsychInfo database (PsychInfo 11/2000). Mostly, self-regulation is used as an explanatory construct intervening between situational/external factors and individual behavior. In these publications, the term self-regulation refers to a variety of different processes located within the individual regulating behavior, such as social comparison, perceived control, emotional control, delay of gratification, or self-efficacy. Despite the heterogeneity of processes that are subsumed under self-regulation, they have one function in common: they are all concerned with internal processes regulating thoughts, feelings, or actions. Very broadly, self-regulation can be defined as 'the extent to which people influence, modify, or control their own behavior' according to goals or standards (Baumeister and Heatherton, 1996, p. 1; Muraven, 2000).

What goals and standards do people adopt? How do people initiate, execute, and end goal-related actions? Feedback-loop models of self-regulation attempt to answer these questions by referring to cybernetic control processes. Wrosch (e.g., 2003) applied cybernetic models to personal goals. Personal goals can be defined as states a person wishes to achieve, avoid, or maintain. In this context, self-regulation comprises the following three aspects. (1) *Setting of goals and standards*: the setting of goals and standards creates a negative discrepancy of the actual and the desired state that the organism tries to overcome by employing goal-relevant means. (2) *Monitoring*: the comparison of the actual and desired state indicates whether the right means are chosen for achieving one's goals/standards or whether other means need to be employed. (3) *Operation* (goal-pursuit): the initiation, maintenance, and ending of actions for attaining one's goals/standards. There is a large empirical basis supporting the importance of each of these processes for describing goal-directed behavior (see Wrosch et al., 2003, for an overview).

One of the features that make this model particularly attractive is that it elaborates general processes of self-regulation that are not content specific and that can be applied equally well to goals of varying levels of abstractness, including short-term goals (e.g., wanting to dine at a nice restaurant) and to long-term goals (e.g., wanting to become the owner of a nice restaurant). Taking a developmental approach to life management, however, this model has one severe limitation: it starts when goals or standards are already set, and does not explain the process of goal-setting itself. How do people develop and select the goals that direct their behavior? This issue is central for the concept of developmental tasks and age-related expectations that will be discussed in the following section.

Age-Related Expectations as Guidelines for Managing One's Life Across the Lifespan

The question, what kinds of goals a person selects at a certain age, is tightly linked with theories about normative development. These theories suggest that individual development is embedded in an age-sequential order of developmental tasks. In contrast to the very general feedback-loop model of self-regulation, took a highly content-specific approach to life management. According to Erikson's developmental model, there is a sequence of eight developmental stages covering the entire lifespan, each of which is characterized by a specific theme or, in Erikson's terms a 'psycho-social crisis.' According to Erikson, progression to a higher stage can only occur after having successfully solved the previous crises. Examples for such crises are 'identity versus identity diffusion' in adolescence and 'generativity versus stagnation' in middle adulthood. In this framework, life management can be viewed as successfully coping with a sequence of salient themes in each life-phase.

Taking a similar approach to life management, Havighurst introduced the concept of 'developmental tasks' referring to 'a task which arises at or about a certain period in the life of the individual, successful achievement of which leads to his happiness and to success with later tasks, while failure leads to unhappiness in the individual, disapproval by society, and difficulty with later tasks' (Havighurst, 1972, p. 2). Havighurst proposes a set of about eight developmental tasks for each of the six phases into which he divides the lifespan from 'infancy' to 'later maturity.' Examples of developmental tasks are 'starting a family' for young adulthood, and 'adjustment to retirement' for old age.

The notion of a universal and unidirectional hierarchy of psychosocial crises or developmental tasks has been criticized because it neglects variability between cultures, between individuals, and within individuals (i.e., there is no uniform development across domains of functioning). There is high agreement, however, that within most societies there exist age-related expectations that have evolved from and reflect biological, societal, and historical influences. Such age-related expectations provide information about a timetable of being 'on-time' or 'off-time' (Heckhausen, 2006; Cain, 2009), and a frame of reference regarding the kinds of goals that should be pursued at a given age.

Age-related expectations reflect in part age-graded social opportunity structures (i.e., the amount of resources, support, and reinforcement a society provides for pursuing certain goals for people of a specific age). Complementarily, certain goals are more difficult to strive for when deviating from age-related expectations because necessary resources and support might be less accessible or even negatively sanctioned. In other words, age-related expectations contain information about the likelihood of goal attainment for a given point in the lifespan.

Motivational psychology has shown that the expectation to succeed is one of the key determinants for selecting a goal. In this sense, age-related expectations function as a guideline for adaptive goal selection because they indicate which goals should best be pursued at which point in the lifespan, and which goals should better be abandoned. Empirical evidence supports the notion that individuals select personal goals that are congruent with the age-related structure of the lifespan.

Taken together, age-related expectations provide a reference standard regarding the kinds of goals that should be pursued at a given point in the lifespan. Moreover, as they reflect age-related opportunity structures, age-related expectations help to guide an individual towards goals for which resources are available and that, therefore, have a higher likelihood of being achieved than 'off time' goals. In this sense, age-related expectations are important guidelines for life management across the lifespan.

Personal Goals as Building Blocks for Life Management Throughout the Lifespan and into Old Age

Action-theoretical approaches view goals as central building blocks of life management because goals structure and direct attention, emotions, and behaviors into particular pathways (Schmuck et al., 2001). Recently, a number of models have stressed the importance of goal-related processes for developmental regulation and life management. In the author's view, the currently most prominent models are the model of selection, optimization, and compensation (SOC-model), the model of optimization in primary and secondary control (OPS-model), and the model of assimilative and accommodative coping. In this section, how these complementary models – that all have received good empirical support – conceptualize life management is briefly presented.

The SOC-model (Baltes & Smith, 2003) posits that, throughout the lifespan, individuals continually seek to successfully manage their lives through the orchestration of three processes of developmental regulation: selection, optimization, and compensation.

The importance of selection of goals is based on the assumption that, throughout the lifespan, biological, social, and individual opportunities and constraints specify a range of alternative domains of functioning. The number of options, usually exceeding the amount of internal and external resources available to an individual, needs to be reduced by selecting a subset of these domains on which to focus one's resources. Selection (i.e., developing, elaborating, committing to goals) gives direction to development by guiding and focusing resources on certain domains of functioning (specialization). Moreover, goals organize behavior into action sequences and reduce the complexity of a given situation as they guide attention and behavior.

According to the SOC-model, by delineating the range of goals on which to focus one's resources, selection is the first important step for successfully managing one's life. To actually achieve higher levels of functioning in the selected domains (goals), however, optimization needs to take place. Optimization denotes the process of acquiring, refining, coordinating, and applying the means or resources that are necessary to reach the goals envisioned. The importance of optimization is illustrated in the research on expertise. This literature has demonstrated the central role of the deliberate practice of skills, encompassing the acquisition of new skills, the refinement of existing skills, and the integration and automatization of skills for achieving peak-performance. The process of optimization addresses the growth-aspect of development.

The third component of the SOC-model is compensation (see also De Frias et al., 2003). Compensation is aimed at counteracting losses in previously available goal-relevant means and involves substitution of lost means by activating unused means or by acquiring new means. The objective is to maintain functioning in the face of losses of means. A second form of managing losses is to restructure one's goals by focusing resources on the most important goals, adapting goal standards, or substituting no longer achievable goals (loss-based selection). The SOC-model posits that loss-based selection is an important process of life management as it allows one to focus or redirect resources adaptively when other means for the maintenance of functioning substituting the loss (compensation) are not available or would be invested at the expense of more promising goals.

According to the SOC-model, although all of these processes have positive developmental functions, it is their orchestration that contributes mostly to adaptive life management in the face of changing developmental opportunities, demands, constraints, and personal needs.

Building on the SOC-model and focusing on control, Heckhausen (2006) propose in their model of optimization in primary and secondary control (OPS-model) two modes of control jointly contributing to life management across the lifespan, primary and secondary control. According to the OPS-model, people have an innate need to control their world and try to maximize their control potential. Primary control encompasses instrumental efforts to modify the environment according to one's goals. Secondary control is employed when primary control strategies directed at the external world are not available or fail. Secondary control focuses on internal aspects such as changing one's goals, engaging in self-protective attributions, or social comparisons. Heckhausen distinguish between selective and compensatory forms of primary and secondary control strategies. Selective primary control refers to the investment of means for goal achievement. Compensatory primary control denotes the employment of external resources (e.g., help of others) or the acquisition of alternative means when available internal resources are insufficient.

Selective secondary control refers to enhanced selectivity of resource investment into existing goals. Compensatory secondary control denotes cognitive reframing of goals such as devaluation of unobtainable goals. According to the OPS-model, life management is only optimized when the four types of control are orchestrated according to an individual's developmental ecology.

A similar view proposed people use two complementary forms of coping to achieve a match between the actual and the desired developmental state, assimilation, and accommodation. Assimilation denotes an actional mode of coping that is characterized by tenaciously pursuing one's goals by modifying the environment according to personal goals. Accommodation

refers to a nonintentional, unconscious mode of coping, namely flexible goal adjustment. Accommodation comprises changing, downgrading, or discarding personal goals or lowering one's level of aspirations to match the environment. People will first use assimilative strategies to close the mismatch between the actual state and personal goals. When assimilative attempts fail, a gradual shift to the accommodative mode occurs, first by investing additional goal-related activities, then by engaging external aids or support systems, and, finally, by adjusting standards or even disengaging from goals (e.g., Brandtstädter et al., 2002).

The three models reported above converge in the importance they place on goals and motivational processes as building blocks of life management. Moreover, these models suggest that key processes of life management across the lifespan lie in the adaptation to developmental ecologies by opportunity-oriented selection, focused investment of resources, and compensation of losses. Age-related changes in the availability and efficiency of resources necessitate the flexible use of goal related strategies.

Starting out to be highly positive in childhood through early adulthood, the ratio of gains to losses becomes less favorable with age. Thus, with increasing age, individuals need to allocate more resources into the maintenance of functioning and compensation of losses than into growth. Life management, following these models, encompasses optimizing developmental potential and simultaneously compensating for losses.

Outlook

Different lines of research inform us that one important way in which individuals manage their lives is by developing, committing to, and pursuing a set of (life-) goals. What goals a person selects and pursues is embedded in sociocultural, biological, and phylogenetic factors.

An interesting question awaiting empirical investigation is the relative importance of these factors across the lifespan. During childhood, adolescence, and young adulthood, biological constraints and social expectations regarding the kinds of goals to be pursued are relatively strong. In late adulthood and old age, there are fewer normative age-related expectations. This relatively greater social freedom might strengthen the impact of personal goals for life management. At the same time, in old age resources needed for shaping one's environment according to personal goals decline. Therefore, it seems particularly crucial to focus on goals that are both personally very important and for which resources are still available. Future investigations of the interaction of the various factors influencing the selection, pursuit, and maintenance of goals across the lifespan might increase our understanding of how people manage their lives.

Life Table

Jan M Hoem, The Max Planck Institute for Demographic Research, Rostock, Germany

Abstract

In this article, modern statistical language is used to explain the basic notions of the oldest tool of demographic analysis, namely the life table. Following a long tradition in which demographers seek to establish sensible results out of a suboptimal data set, a real-life example is used to describe how one might produce a simple life table in the presence of digital preference (age heaping, grouped time reporting). An extension to multiple-decrement (or competing-risk) life tables is also provided.

The life table is perhaps the oldest tool developed for the analysis of survival patterns in human and other populations. Its roots go back at least to the famous book on the English Bills of Mortality that John Graunt published in 1662, a book that is sometimes cited as the beginning of systematic statistical science. Life-table techniques are described in detail in most introductory textbooks on the methods of actuarial statistics, biostatistics, demography, and epidemiology (see, e.g., Chiang, 1984; Elandt-Johnson and Johnson, 1980; Manton and Stallard, 1984; Hinde, 1998; Preston et al., 2001). In this article the basic notions of life-table construction are explained with a focus on issues that are sometimes underemphasized in other accounts. More of the underlying mathematical theory can be found in Hoem (1998) and in the textbooks. For the history of the topic, consult Seal (1977), Smith and Keyfitz (1977), and Dupâquier (1996).

A Cohort Life Table

Classical presentations of life-table techniques typically start with data in a format like that of the first four columns in **Table 1**. These particular data come from the Eritrean Demographic and Health Survey of 1995 and show the survival up through their fourth birthday of 7098 girls whose births and deaths were recorded in the survey. This data set is different from normal textbook examples in two ways. First, the data are given for intervals of single-month segments instead of the usual single-year intervals. Second, the present data are subject to strong heaping in the reported age at death for the girls that died. In part this is due to a typical inherent inaccuracy of age reporting in societies like the data source at the time of data collection, and in part due to the fact that (probably for that very reason) only integer years of age attained was asked except for very young ages at death. By contrast, an individual child's age when observation ended (age at censoring) could be computed accurately to the month, for in these data a child's record was censored only because the child's parent was interviewed; the age of a live child could then be calculated from its date of birth. This unconventional data set is used in order to illuminate how a number of practical issues that confront a demographer can be handled in a first analysis of mortality. A more complete investigation would subsequently use intensity-regression methods from event-history analysis (*see* Event History Analysis: Applications), as was done by Woldemicael (1999).

If there had not been any heaping in the reported ages at death, one would calculate $R_x = S_x - \frac{1}{2}(D_x + W_x)$ as an approximate number of person-months of exposure at age x. Here S_x is the number of children who survive to exact age x months, D_x is the number of deaths recorded between exact ages x and x+1 months, and W_x is the corresponding number of records that were censored during this interval. The approximation consists in assigning deaths and interviews to in the middle of the month on average. It has become known as the 'actuarial method.' The next step would be to compute occurrence/exposure rates D_x/R_x (*see* Demographic Techniques: LEXIS Diagram). The age heaping is abundantly evident in the plot of the 'raw' death rates (converted to 'deaths per 1000 person-years') in **Table 1**.

Such age heaping must have been caused by a shift of the real age at death to a reported near-by 'round' anchor age like 3 months, 6 months, or multiples of 12 months. The deaths in some interval $[x_0-a,\ x_0+b]$ around each anchor age x_0 have largely been assigned to the anchor age instead of to each age in the interval, but the total number of deaths $\sum_{t=-a}^{b} D_{x_0+t}$ in such an interval should be largely correct. Similarly, the total exposures $\sum_{t=-a}^{b} R_{x_0+t}$ in the interval should be about right, even though the individual term in the latter sum may be wide off the mark. Under these circumstances it is more sensible to compute death rates for groups of reported ages and list them in the row for the corresponding anchor age. By this reasoning,

$$m_3 = \sum_{x=2}^{4} D_x / \sum_{x=2}^{4} R_x$$

is entered for age 3 months,

$$m_6 = \sum_{x=5}^{7} D_x / \sum_{x=5}^{7} R_x$$

is entered for age 6 months, and so on, as indicated in column 7 of **Table 1**. For the intervening ages x, rates m_x have been computed by linear interpolation. The corresponding curve of rates is given with the label 'grouped' in **Table 1**.

The rest of the life-table computations are based on the following simple mathematical theory. Each individual child i has a lifetime T_i with some distribution function $F(t) = P\{T_i \le t\}$ (with $F(0) = 0$), a probability density $f(t) = \mathrm{d}F(t)/\mathrm{d}t$,

[a]Computed as (sum of deaths)/(sum of exposures) for age groups indicated. (Used for rows where age groups are indicated.)
[b]Computed by linear interpolation.
[c]Additional rows for ages 49–60 months have been deleted.

and a 'force of mortality' or 'death intensity' $\mu(t) = f(t)/\{1 - F(t)\}$. The various lifetimes T_i are independent of each other and they have the same distribution $F(t)$. Simple integration gives $F(x) = 1 - \exp\{-\int_0^x \mu(t)\mathrm{d}t\}$. The death probability is.

$$q_x = P\{T_i \le x + 1 | T_i > x\} = \{F(x+1) - F(x)\}/F(x)$$

from which is derived

$$q_x = 1 - \exp\left\{-\int_0^1 \mu(x+t)\mathrm{d}t\right\} \qquad [1]$$

If one approximates the function $\mu(x+t)$ by the constant m_x for $0<t<1$ (the assumption of piecewise constancy), then (1) gives $q_x = 1 - e^{-m_x}$, which has been used to compute the next-to-last column in Table 1. Finally, a life-table 'survival function' is defined as $\ell(x) = \ell(0)\{1 - F(x)\}$, with $l(0) = 100\,000$. This is the expected number of survivors to exact age x out of an original cohort of $\ell(0)$ initial individuals. Simple manipulation with the definition of q_x gives

$$\ell(x+1) = \ell(x)(1 - q_x), \quad \text{for } x = 0, 1, \ldots \qquad [2]$$

This is a practical recursive formula by which we have computed the final column in Table 1. From the final entry in the $\ell(x)$ column in Table 1 we see that more than 15% of the original cohort of girl babies would die before age 4 (years) according to our data, because $1 - 0.848\,59 = 0.151\,41$.

The mean number of months lived between birth and age n is

$$\mathring{e}_{0:\overline{n}|} = E\min(T_i, n) = \int_0^n \ell(t)\mathrm{d}t/\ell(0) \qquad [3]$$

If one partitions the integral here into a sum of n terms $\int_{x-1}^{x} \ell(t)\mathrm{d}t$ for $x = 1, 2, \ldots, n$, use the trapezoidal rule of numerical integration to see that this integral is approximately equal to $\frac{1}{2}\{\ell(x-1) + \ell(x)\}$, and collect terms suitably, we get the numerical approximation

$$\mathring{e}_{0:\overline{n}|} \simeq \left\{ \sum_{x=0}^{n} \ell(x) - \frac{1}{2} - \frac{1}{2}\ell(n) \right\} / \ell(0) \qquad [4]$$

The girls in the Eritrean data set lost 5 months of life on average before they reached their fourth birthday, for according to eqn [4] with $n = 48$ months they experienced a mean lifetime of 43 months.

Other Life-Table Procedures

Life-table construction consists in the estimation of parameters and tabulation of functions like those above from empirical data. The data can be for age at death to individuals, as in the illustrative example, but they can also be observations of duration until recovery from an illness, of intervals between births, of time until breakdown of some piece of machinery, or of any other positive duration variable. In general, a T_i is the duration until occurrence of some event that ends individual survival in a given status. The method of estimation depends on the character of the data. If accurate (ungrouped) individual-level data are available, then the Kaplan–Meier estimator (*see* Event History Analysis: Applications) can be used to estimate $\ell(x)$ for all relevant x, and estimates of the other life-table functions can then be computed subsequently. Alternatively a segment of the Nelson–Aalen estimator can be used to estimate each integral $\int_0^1 \mu(x+1)\mathrm{d}t$.

Equation [1] can then be used to estimate q_x for each integer x, and the rest of the computations follow suit. Sometimes the force of mortality is represented by some function $h(x;\theta)$, where θ is a vector of parameters. For instance, actuaries often use the classical Gompertz–Makeham function $h(x; a, b, c) = a + bc^x$ for the force of mortality in their life tables (*see* 'Demographic Models; Population Dynamics: Probabilistic Extinction, Stability, and Explosion Theorems).

From any given schedule of death probabilities $q_0, q_1, q_2, \ldots$, the $\ell(x)$ table is easily computed using the recursive eqn [2]. Much of the effort in life-table construction is, therefore, concentrated on providing a schedule $\{q_x\}$.

So far, this account has assumed that the data come from a group of independent individuals who have all been observed in parallel, essentially a cohort that is followed from a significant starting point (namely from birth in our empirical example) and that is diminished over time due to 'decrements' ('attrition') caused by the risk in question and also subject to reduction due to censoring. The empirical example displayed data only for the first 4 years of life of such a cohort. One would have had to follow the cohort until the end of the cohort's total life to produce a 'complete cohort life table.' It is more common to compute a q_x schedule from data collected for the members of a population during a limited time period and to use the mechanics of life-table construction to produce a 'period life table' from the q_x values. If real mortality patterns are tied to cohorts, individuals who live at widely differing ages in the observational period do not normally have the same risk structure, and the period taken by the life table to reflect the patterns of a 'synthetic (fictitious) cohort' exposed to the risks of the period at their various ages.

Whichever way the life-table survivor column has been produced, eqn [4] can always be used to calculate mean numbers of time-units lived under the risk for which the life-table was constructed. If the time unit is a year and n is chosen so large that no one lives more than n years (symbolized by letting $n = \infty$ and $\ell(\infty) = 0$), $\mathring{e}_{0:\overline{\infty}|}$ is called the 'life expectancy' of the life table and is normally denoted $\mathring{e}_0$. The subscript 0 indicates that the calculation is made for a newborn individual. Similar computations can be made at any age x and one gets expected remaining lifetimes of the form $\mathring{e}_{x:\overline{n}|} = \int_0^n \ell(x+t)\mathrm{d}t/\ell(x)$, with approximation formulas similar to eqn [4].

Multiple-Decrement Tables

When suitable data are available, the risk of death (or force of mortality) may be partitioned according to mutually exclusive causes of death. Let $\mu_k(t)$ be death intensity or force of mortality for cause k at age t, and let the total force of mortality be $\mu(t) = \sum_k \mu_k(t)$. Then the probability that an individual who is alive at age x will die from cause k before age $x+1$ is

$$q_x^{(k)} = \int_0^1 {}_tp_x \mu_k(x+t)\mathrm{d}t \qquad [5]$$

where ${}_tp_x$ is the probability of surviving to age $x+t$ for an individual who is alive at age x. For given risk intensities $\{\mu_k(\cdot)\}$, $q_x^{(k)}$ can be computed by numerical integration in eqn [5]. A corresponding column of $q_x^{(k)}$ values may then be added to the life table for each k, and other cause-specific life-table

functions may also be computed. Note that $q_x^{(k)}$ is influenced by risk intensities other than $\mu_k(\cdot)$, for

$$ {}_tp_x = \exp\left\{ -\sum_j \int_0^t \mu_j(x+s)\mathrm{d}s \right\} $$

where the exponent depends on all $\mu_j(\cdot)$, including those for $j \neq k$.

Several further life-table functions can be defined by formal reduction or elimination of one or more of the risk intensities in formulas like eqn [5]. In particular, a 'single-decrement life table' can be computed for each cause k in order to show what the life table would look like in the hypothetical case where this cause was the only one operating in the study population and where it did so with the risk function estimated from the data. The purpose is to see the 'pure' effect of the risk in question on a fictitious cohort without interference from other causes. (The decrement probabilities and other features of the single-decrement life table do not depend on any other intensities than the one for which the table is computed.) This does not mean that one should believe that the total risk intensity can actually be reduced to the risk in focus or that this risk operates independently of other causes.

Most single-decrement life-table functions have straightforward interpretations. If, for instance, $\ell_k(x)$ denotes the corresponding survival function, then $\ell_k(x)/\ell_k(0)$ is the probability of surviving to age x in the fictitious table. Suppose, for example, that the study population is a group of unpartnered individuals subject to the competing risks of marital and nonmarital union formation as well as to the risk of death. One can then compute a single-decrement life table based on the risk of transition into a nonmarital union alone and find the probability that an individual would end up in such a union by age 50 years, say, if marriage were no alternative and death did not operate, even though in reality marriages continue to be formed by group members and unpartnered individuals continue to die. In such a table one may get $\ell_k(\infty) > 0$ because the event never occurs to some individuals, even if it operates alone. (We will all die but some individuals never enter a nonmarital partnership even if they live to age 100 years.)

Life expectancies $\mathring{e}_{15:\overline{n}|}$ computed in the three-decrement life table would be interpreted as the mean number of years (say) lived in the unpartnered state between ages 15 and $15+n$ years. In the single-decrement life table for nonmarital-union formation, one possibility is to compute the mean age of entry into a nonmarital union only for those who do enter such a union by age n, that is, the conditional mean.

$$ \int_0^n \ell_k(x)\mathrm{d}x / \{\ell_k(0) - \ell_k(n)\} \qquad [6] $$

Conversely one can compute a 'cause-deleted life table' by eliminating one or more of the cause intensities in the formulas. To 'remove' cause k, introduce $\mu_{-k}(t) = \mu(t) - \mu_k(t)$ and construct a 'normal' life table by replacing $\mu(t)$ by $\mu_{-k}(t)$ everywhere. This would show what the life table would look like if it were possible to eliminate cause k without changing the risk of any other cause. It could be used for example to see how partnering probabilities would appear if the partnering process were undisturbed by mortality. One would then remove the force of mortality from the life-table formulas and operate only with the sum $\mu_{-k}(t)$ of the intensities of marital and nonmarital union formation in the computations. Note that this is again a purely hypothetical construct; in fact it is counterfactual for mortality cannot of course be completely removed.

Life expectancies can be calculated for a cause-deleted life table as for any other life table. If $\ell_{-k}(x)$ is the table's survival function and $\ell_{-k}(\infty) = 0$, then a formula for the cause-eliminated life expectancy is $\mathring{e}_0^{(-k)} = \int_0^\infty \ell_{-k}(x)\mathrm{d}x/\ell_{-k}(0)$. The classical applications were to cause-of-death removal, and the difference $\mathring{e}_0^{(-k)} - \mathring{e}_0$ was interpreted as the (fictitious) gain in life expectancy produced by removal of cause k. For example, Westergaard (1907) found that according to the English life tables of 1881–90, life expectancy for females would increase by 2.7 years if tuberculosis deaths could be eliminated, by a year if cancer deaths could be removed, and by 1.1 years if deaths due to diarrhea and dysentery could be deleted separately. The effects were not additive, and if all three cause-of-death groups could be removed, the gain would be 5.6 years and not 4.8. The life expectancy for females in the original table was $\mathring{e}_0 = 47.2$ years.

This article is a revision of the previous edition article by G. Fischer, volume 13, pp. 8836–8840, © 2001, Elsevier Ltd.

Abstract

This article provides an overview of the use of new technologies for lifelong learning. While in the past learning technologies were mostly provided by educational institutions to support a specific lifetime or shorter learning episodes, nowadays more personal technologies are used for lifelong learning to support self-organized learning. Four important developments are introduced in this article, namely, open learner models and learning analytics, learning networks and networked learning, open educational resources and practices, and last but not least, mobile and contextualized learning. The state of the art in these research fields is summarized and the future potential and requirements for lifelong learning are highlighted.

Introduction

Lifelong learning is a concept that integrates a wide variety of learning formats and is usually seen as education throughout the lifetime. Lifelong learning activities can happen in a formal context (organised by an educational institution), it can happen outside an educational institution (nonformal), or it can happen accidentally without previous planning (informal). Any purposeful learning activity undertaken on an ongoing basis targeted at the increase of knowledge, skills, and competences can thus be seen as lifelong learning. Longworth (2003) stresses the importance of lifelong learning for the twenty-first century because of global demographics, environmental imperatives, the pervasive access to information due to new technologies, and the speed of innovation in science and technology. Due to these factors it becomes, more and more, a necessity to not only equip people with knowledge in educational institutions but to also prepare them to update their knowledge, skills, and competences and take responsibility for learning throughout their lives. The author identifies the dismantling of barriers to lifelong learning as an important action point to be addressed by research and developmental activities and by society as a whole. Among others the author identifies the following barriers to lifelong learning:

- Poor family culture of learning
- Lack of finance to participate in lifelong learning
- Learning providers not geared to the needs of learners
- Poor information services for attracting people to learning
- Distance from the educational provision
- Lack of facilities to study at home
- Perception that the benefits system discourages learning

These identified barriers are also confirmed by recent statistics from the Labor Force Survey of the European Commission (Eurostat, 2012). This survey shows that in Europe between 2006 and 2011, there was a decrease in participation in lifelong learning activities. Participants in this survey mention access, time, place, and lack of personalization as barriers to involvement in lifelong learning activities. This survey shows that there is a gap between the societal relevance of lifelong learning and the daily practices of professionals. An overall fragmentation can be added as an additional barrier to lifelong learning.

While learning technologies have been traditionally offered by educational institutions with a focus on supporting short learning episodes, little attention has been given to support the complex array of contexts, life spans, and the individual characteristics of learners. Koper and Tattersall (2004) argue that in the past, the timescales and the episodic and multi-institutional nature of lifelong learning were not reflected in mainstream learning technologies.

In the field of technology-enhanced learning (TEL), a number of research directions have been developed in the last few years that help to address the problems lifelong learners are facing today. In this article I introduce the current state-of-the-art of new technologies for lifelong learning. For this purpose four research topics are introduced that contribute to the dismantling of barriers for lifelong learning. These new technologies are open learner models and learning analytics; learning networks and networked learning; open educational resources (OER) and practices; and last but not least, mobile and contextualized learning. In the following paragraphs, I introduce the current state-of-the-art in these research topics and discuss their contribution in addressing barriers for lifelong learning. Finally, I provide an outlook on future research and development as well as the implications for policy frameworks for lifelong learning.

Open Learner Models and Learning Analytics

One of the challenges in the field of TEL is the modeling and recognition of the activities and contexts of learners. Since lifelong learners might constantly change their learning context, location, goals, learning environments, and also learning technologies, the recognition of the current situation of the learner with the goal to personalize and adapt the learning environment is not only a challenging but also a promising research direction. A lifelong learner might start his day during travel, with the reading of a work-related textbook on his tablet computer, continue during work with a discussion of a specific problem in a professional social network, and join in the evening an online master class about a new topic in

which he would like to build expertise. These short learning episodes during 1 day are a representative picture of lifelong learning as a whole. Learners are active in different learning contexts, in different learning formats, and with different learning technologies. The analysis, construction, and recognition of the learner context have been treated traditionally under the topic of learner models from the perspective of adaptive hypermedia (AH) (Brusilovsky et al., 2007). Based on an analysis of the activities and contexts of learners, algorithms have been developed that are able to predict the behavior of a learner, to provide guidance for the learning process, or to personalize the presentation of learning content. But there is one important limitation in this work. The data collection and rationale governing these data work well in closed contexts like a dedicated electronic learning environment (e.g., learning management system/course management system). But there are limitations when it comes to integrating data from different learning contexts as presented above. This problem has been discussed as the 'open corpus problem' (Brusilovsky and Henze, 2007). Open corpus AH do not work on the closed set of resources known at the design time but rather, work on the assumption that the learning resources and learning context constantly change and evolve.

To address this problem and to enable personalization, several initiatives have been started for lifelong learner modeling. A learner model is the sum of all knowledge that a software system has about a learner. This model gets constantly updated during learning activities and should thus reflect the current state of knowledge of the learners. While traditional learner models were closed and only used by the technological infrastructure, recently open learner models for the use of the learner have been proposed and evaluated. The current state of such a learner model is presented to the user and there are different ideas about the benefits and the management of such an open learner model. Bull and Kay (2010) describe independent open learner models as being fully controlled by learners instead of learner models controlled by a system or in a cooperative manner. This approach addresses the personalization barrier of lifelong learning on a technological level and gives learners control about their digital representation in a learner model.

Kay (2008) takes this approach one step further and proposes to link and aggregate learner models from different contexts into long-term learning models that integrate the different contexts of lifelong learners. Besides the issue of collecting and storing these data, she also proposes to integrate representations of the lifelong learner models into the working contexts of lifelong learners. This direction is also explored in a relatively young research topic in the field of TEL called 'Learning Analytics' (Greller and Drachsler, 2012). Learning analytics exploit the potential of available large data sets (about learners, courses, behavior, etc.) to provide feedback in the form of meaningful visualizations to different stakeholders (learner, teacher, organization). While several initiatives in the field remain in the traditional boundaries of educational segments or institutions, some authors propose a more open approach to learning analytics that is potentially useful in the context of lifelong learning (Buckingham Shum and Fergusson, 2012). Approaches in which learners' activities are monitored and collected in a number of different TEL environments have the special potential to help learners to connect different learning contexts (Romero-Zaldivar et al., 2012). Thus, open learner models and learning analytics represent new technological solutions that can help learners to connect their data from learning activities in different learning environments and contexts, and contribute to the dismantling of the personalization barrier of lifelong learning.

Current research focuses on the potential of open learner models and learning analytics to increase awareness about the learning process itself and its effects on meta-cognition. On the other hand, the evaluation contexts chosen mainly focus on the context of educational institutions, and the transfer of results to an authentic lifelong learning context cannot be done without limitations. One limitation for both approaches presented here is a relatively high visual literacy requirement in order to make use of the data representation provided. Therefore, some of the issues in open learner models and learning analytics are related to advancement of visualization approaches for learners and learning activity data.

Learning Networks and Networked Learning

The networked society and the potential to use network effects for learning and competence development have motivated new initiatives to apply this potential to the context of lifelong learning. Koper et al. (2005b) propose the following model of a learning network: "An ensemble of actors, institutions, and learning resources, which are mutually connected through and supported by, information and communication technologies in such a way that the network self-organizes and thus gives rise to effective lifelong learning." **Figure 1** shows this conceptual model (Koper and Tatersall, 2004).

The model consists at its core of collections of learning activities around a specific domain. Learners in this network are connected via their shared learning objective (called the target) and they can optionally receive assessment and certification. The authors derive several requirements for the technical development of learning networks for lifelong learning. These requirements are as follows:

- Learners should be responsible for their own learning and they should be able to conduct learning activities in different contexts at the same time. Thus, the learners should be put at the center of the stage and should be able to take self-directed action.
- The focus of the learning network should be to enable learning and not to support instruction.
- Learners should be enabled to connect formal, nonformal and informal learning activities.
- Learning networks should allow access to learning resources and activities from different providers.

This model has been translated into an architectural model to allow its technical implementation. While initially peer-to-peer technologies were used for implementation (Koper et al., 2005), later this model was integrated based on the service-oriented architecture paradigm. A number of technical services have been developed to support learners in learning

Figure 1 Model of a learning network.

networks. The individual routes of learners through this learning network are called 'learning paths.' To avoid unnecessary repetition and to support personalization, a positioning service has been developed (Kalz et al., 2007). This service has been built on the basis of accreditation for prior learning and has used language technologies to approximate the learner's position, based on a similarity analysis between the learner portfolio and the resources in the learning network. Based on the position of a learner in this network and the emerging behavior of other members in this network, the next 'best learning' activities can be recommended (Janssen et al., 2007). Drachsler et al. (2008) discuss the complexity and requirements of using recommender systems in learning networks. Recommender systems are a well-known approach for the acquisition of products or media items for users; but to use recommender systems in learning networks, a more complex set of requirements is required, due to interdependencies of learning resources and learning activities. The model of learning networks has been implemented, tested, and extended by a number of technical services in the European project 'TENCompetence' (Koper and Specht, 2008), afterward used as technical infrastructure for innovative educational projects in different countries.

Alternatively, other authors have proposed the concept of networked learning. Networked learning is more loosely defined in comparison with the learning networks approach. Networked learning is regarded as learning in which information and communication technology is used to enable connections between learners, learners and tutors, the learner and learning resources, and the learning community as a whole (Goodyear, 2001). Recently more attention has been given to the role of online social networking platforms and their potential for learning and competence development. Veletsianos and Navarrete (2012) provide a review of the literature on the use of social networking sites for learning and present a case study to analyze the experiences of students in courses delivered via social networking sites. The study showed that learning in social networks can help to decrease problems of isolation and lack of support in networked learning contexts. Due to the widespread adoption of social software and social media, their potential for lifelong learning has been explored from the perspective of self-directed learning. Dabbagh and Kitsantas (2012) propose the use of personal learning environments in combination with social media to allow the learner three type of activities that are important for self-organized learning. In their framework, the phases of personal information management, social interaction and collaboration, and information aggregation and management play a central role.

The approach of learning networks and networked learning has been applied in a number of contexts. These case studies have mostly been implemented in the professional development context, to allow professionals a flexible and self-directed access to learning resources and experts in the profession. A limitation for learning in learning networks and networked learning is that a relatively high level of self-organization and at the same time technology literacy is needed to be able to organize one's learning process based on a combination of tools.

To sum it up, learning networks, networked learning, and approaches based on the use of social networking platforms, social software, and social media, offer new contexts for lifelong learners to learn, regardless of time and place, and to be active in a social context while focusing on self-organized

learning. These new technologies contribute thus to the dismantling of the barriers of time, place, and personalization for lifelong learning but also need a relatively high level of technology literacy and self-organization competences. They have the potential to address the fragmentation problem of lifelong learning; but on the other hand, the networked approach, by and large, does not lead to centralization but to a complex array of tools and resources.

OER and Open Education

One of the developments that specifically contributed to decrease the accessibility barrier of lifelong learning is the trend to publish learning resources as OER. While traditionally learning resources have not been made available to the public, several initiatives have been started in the last 10 years that have focused on making learning resources publicly available. These initiatives have partly been motivated by the need to increase student recruitment, to maximize access to learning resources, to help disadvantaged communities of learners, and finally to give to the public what it has paid for. The last argument stems from a wider discussion about open access for scientific work financed by public resources.

The Organisation for Economic Cooperation and Development (OECD) Center for Educational Research and Innovation argues that OER are governmental means to support lifelong learning, representing a cost-effective way to ensure access to a diverse set of learning opportunities (OECD, 2007). The OER initiatives have been conducted in three different cycles. Initially, some large institutions of higher education, like MIT, started to publish learning resources publicly on the Internet, without charging access fees. Several other institutions followed this example. The vast amount of resources thus available on different platforms, motivated a second stage of development, in which the access and search of domain-specific, OER was targeted. Several technical standards have been developed to ensure that learning resources are accessible to end users (Klemke et al., 2010). A third stage has changed the focus again from the resources to the learning process as a whole, to enable open educational practices (Kalz et al., 2008). While the first and second stages have primarily focused on making isolated and reusable learning resources available and accessible, the third stage was motivated by the need of learners for an educational framing and the embedding of the learning resources in a wider learning process and context. Geser (2007) has stressed in the roadmap deliverable of the Open eLearning Content Observatory Services project, the need for new educational practices that go beyond OER use and reuse. The embedding of OER in competence-focused, collaborative knowledge-acquisition scenarios is sketched as a promising future doorway to let open educational practices emerge. Recent research and development projects have not only made OER available, but also offered new technical services to integrate these learning resources into individual competence-development trajectories or have enabled the reuse of learning resources with social media (e.g., Kalz et al., 2010). Thus OER can potentially be used in self-directed learning scenarios, as described in earlier paragraphs.

In general, open universities around the world have a long tradition of offering open learning opportunities to diverse audiences. But the Internet and OER have enabled new actors to be active in the field of open distance learning. More recently the concept of 'Massive Open Online Courses' (MOOCs) has been intensively discussed. This new format is a continuation of OER initiatives but with a focus on enabling open educational practices. Daniel (2012) discussed this new educational format critically and he stressed the adaptation of the original model of MOOCs. While the initial idea of MOOCs was centered on networked learning and cocreation of knowledge, recently several campus-based institutions have taken the initiative to implement their own MOOC concept. In this case the MOOC concept has been implemented based on an instructional paradigm with a focus on knowledge transmission via recorded lectures.

The scholarly discussion about this format is at a very early stage. Nonetheless, the speed of adoption of MOOCs has again contributed to the diversification of learning resources available to the public without access costs. While the concepts of OER and MOOCs both focus on enabling open access to learning resources and learning activities, there are potentials and limitations for both concepts. The idea of OER was not only to provide open access but also to allow adaptation of the published material under a licensing scheme like Creative Commons. This licensing scheme enables producers of digital resources to implement a fine-grained regulation of the reuse and adaptation allowed for their resources. This has enabled other teachers and learners to use existing material instead of developing something from scratch. Through the reuse goal, the resources published were mostly as context-neutral as possible, to allow adaptation for different contexts. The assumption for reuse of OER was that these resources are found, adapted, and integrated into a new learning context. The situation for MOOCs is exactly the opposite: While both formats allow open access, the concept of reuse available in OER is not given in the MOOC context. Instead, the focus of MOOCs is rather on cocreation of knowledge without a focus on learning content; or the implementation realizes a classical lecture-based model that follows a classical instructional paradigm without any reuse of resources.

To sum it up, OER and open education have addressed the accessibility barrier and the financial barrier for lifelong learning. A number of initiatives have shifted from open access and reuse of resources to enable new open educational practices. While the scholarly discussion about the effects of these new approaches is not yet mature, these initiatives increase the diversification of opportunities for lifelong learning.

Mobile and Contextualized Learning

The pervasive use of mobile devices on a global scale and in nearly all contexts of life has contributed to a growing interest in mobile and contextualized learning scenarios. While mobile learning was regarded in its early years from a technocentric perspective, later the focus shifted more to the mobility of the learner (Traxler, 2009). Mobile technologies are available whenever learning and learning needs occur to people. Thus it enables people to connect their fragmented learning

experiences to their long-term learning goals. This offers the opportunity to connect the unconnected learning contexts of lifelong learners; mobile and contextualized learning scenarios can bridge the work context and the learning context. This bridging function of mobile learning has been described by Wong and Looi (2011) as an agenda for research into seamless learning. A seam is always present when there is a change in the context of the learner. The following seams that mobile and contextualized learning should address have been identified as subjects for research:

- Encompassing formal and informal learning
- Encompassing personalized and social learning
- Learning across time
- Learning across locations
- Ubiquitous knowledge access
- Encompassing physical and digital worlds
- Combined use of multiple device types
- Switching between multiple learning tasks
- Knowledge synthesis
- Encompassing multiple pedagogical or learning activity models

These issues have also an impact on how lifelong learning is organized and conducted today and many seams of this research agenda are directly related to the barriers identified earlier.

Sharples (2000) argues that lifelong learning is always situated, can focus on different learning activities, and can happen in different learning contexts. Tools that support lifelong learners should therefore be highly portable, individual, unobtrusive, available, adaptable, persistent, useful, and intuitive. He discusses the convergent development of personal technologies and changing notions of lifelong learning. **Table 1** presents the convergent development of new communication technologies and lifelong learning (Sharples, 2000).

In a recent meta-analysis of mobile learning, it was shown that most studies in the field are conducted in higher educational institutions and elementary schools (Wu et al., 2012). This means that the lifelong learning context is not yet in the focus of attention, despite the convergence of requirements for lifelong learning and the development of new personal technologies.

To enable the vision of seamless learning experiences, the core task is to identify the key parameters that influence the learning processes and the technical consequences of developing mobile solutions to support a seamless learning experience. Besides appropriate educational content, contextualization, personalization, interaction, awareness, and reflection are the main inputs required to realize seamless learning experiences. Recently, nonformal, informal learning contexts and authentic problems in the mobile and contextualized learning field have been explored. The focus on mobile devices is also shifting to a whole group of personal technologies that could potentially be used in the lifelong learning context (Specht et al., 2012).

To sum it up, mobile and contextualized learning and the use of personal technologies have the potential to contribute to the dismantling of the fragmentation of lifelong learning activities. They support the mobility of learner and contribute to time- and place-independent access to learning resources and activities. Several case studies from disadvantaged learning communities show that they also have the potential to also address the lack of study facilities at home.

Table 1 The match of new communication and information technology to lifelong learning

Lifelong learning	*New technology*
Individualized	Personal
Learner centered	User centered
Situated	Mobile
Collaborative	Networked

Connecting the Dots of Technologies for Lifelong Learning

The following table maps the new technologies introduced with the most important barriers (**Table 2**).

Although these developments all have individual value for addressing the barriers for lifelong learning, serious improvements for many individuals will only be visible if these innovations are connected. At the moment, these topics and technological developments are still studied and developed relatively independently from each other – sometimes even in different scientific communities.

Besides these different problem areas, there is also a time perspective in the challenges presenting for technological support of lifelong learning activities. In the third age of life (also called 'older adulthood'), new requirements for learning can arise through specific health conditions. On the one hand, these requirements can be addressed by following so-called web accessibility guidelines; on the other hand, the target group of learners in later lifetime has different cognitive abilities and attitudes toward the use of new technologies

Table 2 Mapping of lifelong learning barriers and new technologies

Barrier for lifelong learning	*New technology*
Lack of finance	Open educational resources/open educational practices
Lack of personalization	Modeling of lifelong learning/open learner models and mobile and contextualized learning
Time/place	Learning networks/networked learning and mobile learning
Lack of facilities to study at home	Mobile and contextualized learning
Fragmentation	Mobile and contextualized learning/learning networks and networked learning
Health/age	Open learner models and accessibility tools

(Czaja et al., 2006). Personalization approaches for this target group have to take into account these specific requirements. Therefore, recently new initiatives have been started with a focus on providing learning opportunities for elderly people. These initiatives not only focus on the acquisition of new skills or knowledge but there is also a trend toward developing learning technologies to maintain cognitive abilities.

But these connections can only emerge if there are policy frameworks that support and foster lifelong learning for large parts of society and encourage the development of new business models for companies that support learners in lifelong learning or in learning activities that are accessible and compliant with requirements of lifelong learning. One of the largest framework programs to foster the advancement of lifelong learning is the Lifelong Learning Program developed by the European Commission. This framework needs to be combined with national initiatives to balance the societal relevance of lifelong learning and the participation in lifelong learning activities by a large part of the society.

Conclusions and Outlook

In this article, I have provided an overview of recent developments in the use of new technologies for lifelong learning purposes. These new technologies help to dismantle barriers to lifelong learning. An overall challenge for the development and evaluation of technology for lifelong learning is the evaluation context: While the context of lifelong learning is described as being episodic and multi-institutional, most evaluation contexts lack this important feature; thus scientific evidence is collected in the context of educational institutions and in a relatively short time span. In the future, more field studies and long-term evaluation scenarios, which focus on mobility problems and seamless learning experiences of lifelong learners in authentic contexts, are needed.

Another challenge to the use of new technologies for lifelong learning is the level of self-organization and self-directedness required to use these technologies to organize one's own learning. While educational institutions have an emphasis on knowledge transfer, more emphasis needs to be placed on the use of new technologies for self-directed learning. This issue is seen as one of the key skills for our society but educational institutions have not yet adapted to prepare people not only for a lives as professionals, but also for lives as lifelong learners.

Abstract

Life span developmental psychology is the study of individual development from conception until death. The hallmark of this approach is the coconstruction of biology, society, and the individual to produce development. Individuals actively regulate their development according to opportunities and constraints in their social ecology. Life span development theories address the impressive ability of individuals to optimize their development across the life span through the use of three central processes of developmental regulation: goal engagement, goal disengagement, and metaregulation.

Life span developmental psychology (or life span psychology) is the study of individual development (ontogenesis) from conception until death (Baltes, 1987, 1997). The life span view of human development capitalizes on the capacity of individuals to successfully adapt to the environment and optimize development across the life span. This article provides a historical background of the field as well as key propositions, major theories, current methods, and future research areas.

Historical Background

The beginnings of the field of developmental psychology date back more than 200 years ago when Johann Nicolaus Tetens (1736–1807) published a two-volume work on human nature and its development in 1777 (Baltes et al., 2006). This work covered the life span of human development and included several of what we now regard as key tenets of life span development theory. In the first few decades of the 1900s, Charlotte Bühler (1893–1974) picked up this thread and contributed groundbreaking conceptual and empirical work about the development of children, adolescents, and older adults (e.g., Bühler, 1933).

Despite a long history in Germany, what emerged as developmental psychology in North America and other areas of Europe around 1900 was distinct from the vision of Tetens and his predecessors. Influenced by biology, evolution, and genetics via Darwinism at the turn of the century, early North American developmental psychology was dominated by conceptions of maturation and growth with an almost exclusive focus on child and adolescent psychology and development.

Modern life span developmental psychology emerged in the late 1960s through the work of Hayne Reese, K. Warner Schaie, Paul B. and Margret Baltes, John R. Nesselroade, Richard M. Lerner, and their colleagues (Baltes, 1979b; Baltes et al., 1980; Lerner et al., 1983). In the 1970s and 1980s, life span psychology as a field was established with a series of conferences on the subject held at the University of West Virginia (Goulet and Baltes, 1970) and the publication of multiple volumes on life span research (e.g., Baltes, 1987; Baltes and Brim, 1984; Baltes et al., 1986).

Prior to the establishment of the field, several factors combined to fuel and popularize the life span perspective in the 1960s and 1970s (Baltes et al., 2006). Interest in the field arose from a rapidly aging population and the emergence of gerontology as a discipline. Additionally, participants from large-scale longitudinal studies of child development in the 1920s and 1930s were approaching adulthood and midlife, making it possible to study systematic developmental change across the life span.

At around the same time that life span psychology was gaining popularity as a subdiscipline of developmental psychology, life course sociological perspectives became prominent through the work of developmental psychologist Neugarten (1969), educational scientist Havighurst (1948, 1973), and life course sociologist Elder (1974, 1985) (*see* Life Course: Sociological Aspects). These scholars were pioneers in creating an interdisciplinary framework for research about life span development and the life course. Life span developmental psychology and life course sociology developed parallel to one another, both being heavily influenced by developmental systems theories (*see* Human Development, Theories of). Both fields emphasize the individual as an active agent in his or her development and the dynamic, bidirectional interactions between the individual and the environment over the life span. Not surprisingly, the main difference between the two fields is that life span psychology emphasizes the mechanisms and processes of individual behavioral and mental development, whereas life course sociology focuses on sociostructural and social-institutional conditions for shaping individual life courses.

Metatheoretical Propositions

Several key propositions serve as the foundation for life span development theories (Baltes, 1979a, 1987; Lerner, 1983). Collectively, these principles define the life span perspective and separate it from earlier conceptions of human development. One of the most fundamental of these propositions is that *development is lifelong*. Historically, development was thought to be, by-and-large, complete after adolescence. Current conceptualizations of life span psychology recognize that all developmental periods are important to understanding human development (*see* Human Development, Theories of). Individuals continue to develop and change into old age.

In addition to being lifelong, development is *multidirectional* such that every developmental stage experiences growth and decline, gains and losses. In midlife, for example, adults experience a loss in the efficiency of multitasking (e.g., Kemper et al., 2003; Lindenberger et al., 2000), yet make substantial gains in competency and productivity (Lachman et al., 1994). Even age phases that involve physical and mental decline, such as old age, can witness growth in certain domains of functioning (e.g., language competency and wisdom) (*see* Retirement and Encore Adulthood: The New Later Life Course). In the same vein, periods of rapid growth, like infancy, are prone to losses in certain domains. For example, infants of 4–6 months of age are considered 'universal learners' because they can discriminate between the phonetic differences of all languages (Eimas, 1978; Werker et al., 1981) and between the facial characteristics of even nonhuman primates (Pascalis et al., 2002). However, at around 10–12 months of age, infants experience perceptual narrowing; they can no longer perceive differences in similar phonemes in foreign languages (Cheour et al., 1998; Kuhl et al., 1992; *see* First Language Acquisition: Cross-linguistic). On the one hand, infants gain a more specialized and expert grasp of their own language. On the other hand, they lose the ability to recognize certain sounds in the broad spectrum of speech perception. In this developmental advance, gains are facilitated by losses. Perceptual losses have also been documented in the perception of musical rhythm (Hannon and Trehub, 2005) and cross-species facial recognition.

A characteristic going hand-in-hand with multidirectionality is *multidimensionality* of development. Both gains and losses occur in different domains of functioning and combine to influence overall development. Changes occur broadly in biological, cognitive, and sociocultural domains and more specifically in areas such as memory, perception, motivation, problem solving, emotion, and relating to other people. An example of multidimensional development comes from the psychometric theory of intelligence, which distinguishes two dimensions of intelligence: fluid and crystallized (Cattell, 1971; Horn, 1970, 1989) (*see* Intelligence: Central Conceptions and Psychometric Models). Fluid intelligence refers to the mechanics of the mind: basic information processing tasks that use memory and logic as well as one's ability to problem solve and mentally rotate objects. Crystallized intelligence, on the other hand, is made up of pragmatic functions or cultural knowledge, such as facts, vocabulary, rules, and procedures. These two components of intelligence show distinct developmental trajectories. Fluid intelligence shows steep gains in childhood and adolescence, followed by slow but steady declines in early adulthood and beyond. Crystallized intelligence, by contrast, remains fairly stable throughout adulthood and does not show decline in old age, at least not until very advanced age.

An important criterion for optimal development and aging throughout the life span is to *maximize gains and minimize losses*. The ratio between gains and losses in functioning changes with time such that cumulative losses eventually surpass cumulative gains. In a study by Heckhausen et al. (1989), individuals of all ages perceived and expected significantly more psychological gains than losses during most of adulthood, but toward old age, particularly after 70 years of age, expected losses outnumbered expected gains (see **Figure 1**).

Figure 1 Expectation of fewer gains and greater losses across adulthood. Source: from 'Gains and losses in development throughout adulthood as perceived by different adult age groups' by Heckhausen, J., Dixon, R.A., Baltes, P.B., 1989. Developmental Psychology 25, 109–121.

Perhaps the most important characteristic of life span development is *plasticity*. Plasticity is within-person variability or an individual's capacity for change. Plasticity allows individuals to generate new behavior and adapt to changing biological and societal expectations or challenges throughout the life span. Although humans display an impressive amount of plasticity and capacity for developmental change, there are limits to plasticity (Baltes, 1987; Lerner, 1984). Plasticity is especially challenged after critical or sensitive periods of development. If environmental input or stimulation is not received during this time, the developmental phenomenon is not likely to occur. In the area of language development, for example, mastering the grammar of a new language is extremely difficult if the language is learned after late adolescence (Oyama, 1976).

In speech perception, although the capacity for plasticity declines as development progresses, change can still occur under certain conditions. In the case of cross-species facial recognition, plasticity can be maintained through familiarity and practice (*see* Face Recognition, Psychological and Neural Aspects). For example, 9-month-old infants who had familiarity with monkey faces through picture books were able to discriminate equally well between human faces and primate faces, an ability that is typically lost by this time (Pascalis et al., 2002; *see* Brain Maturation and Plasticity During Infancy and Adulthood). Interestingly, this type of exposure to monkey faces did not work with adults, demonstrating a permanent loss of plasticity.

Researchers are particularly interested in the limits of plasticity for domains that show declines, such as cognitive functioning (*see* Brain Aging (Normal): Behavioral, Cognitive, and Personality Consequences). For example, it is well documented that older adults experience age-related declines in memory and fluid intelligence (Salthouse, 2004; Schaie, 1994) (*see* Cognitive Aging; Aging and Memory). To test plasticity, researchers teach older adults a new set of skills (e.g., the method of loci

memory technique), give them extensive practice using these skills, and assess performance under optimized conditions (e.g., unlimited time to respond) (Baltes, 1993; Willis and Schaie, 1994). The results of studies like these suggest that age-related declines in fluid intelligence are reversible with training, at least for everyday cognitive tasks without time pressure. For example, in a series of training experiments, older adults reached the IQ performance levels of younger adults, although transfer to additional tasks was limited (Willis and Schaie, 1994; Woodruff-Pak, 1993).

When time constraints are placed on everyday tasks and when performance is assessed at the limits of capacity, conclusions about the reversibility of age-related declines are not as optimistic. The 'testing-the-limits' paradigm allows researchers to assess the scope of cognitive plasticity and uncover performance asymptotes of different age groups (Kliegl and Baltes, 1987; Lindenberger and Baltes, 1995). In these studies, younger adults often perform superior to older adults despite extensive training. For example, in a study by Lindenberger et al. (2000), younger, middle-aged, and older adults practiced walking along a complicated path and memorized a list of words at the same time. In all performance measures, older adults incurred increased costs when multitasking. Thus, at the limits of performance, older adults show robust cognitive declines that cannot be reversed with training. In everyday functioning, however, these limits are rarely reached.

The final key characteristic of development is that it is influenced by *contextual factors* (Baltes, 1987). Change occurs in different contexts and domains of development, and is sensitive to universal, individual, and cultural variations. Individuals are embedded in multilevel contexts that include families, neighborhoods, schools, churches, cities, and countries (Bronfenbrenner, 1977, 1979). Each of these contexts is influenced by historical, economic, social, and cultural factors, which are also changing over time. Contexts are dynamic and their interaction with the individual is essential for understanding developmental change.

Influences on Development

One of the objectives of life span developmental theory is to outline the structure and sequence of development as it unfolds over the life span (Baltes et al., 2006). In order to do this, we must understand the factors that influence human development and how they change over time. Human development is a product of the interaction of three factors: biology, culture (or society), and the individual agent. This view of development as the coconstruction of biology, society, and the individual is the hallmark of a modern life span developmental approach. Previous conceptualizations noted two, often dichotomous, influences on development: nature (biology) and nurture (the environment) (Lerner, 2002). The previous entry of Lifespan Developmental Theory similarly specified biology and culture as "the main influences shaping human development" (Staudinger, 2001: p. 8846).

Researchers have long acknowledged the important role of *biology* in guiding development, both growth and decline, through genetic inheritance, physical maturation, physical aging, hormones, temperament, and other mechanisms. Biological factors set timetables for developmental milestones that influence the course of development. For example, women experience menopause between 39 and 59 years of age (median age = 50–52) (Avis, 1999; Rossi, 2004). Because of the rapid decline of estrogen production in the ovaries, women can no longer bear children after menopause. As a result, women typically pursue developmental goals related to childbearing when there are biological opportunities to do so, and disengage from these goals when they are no longer attainable (after menopause or infertility) (Heckhausen et al., 2001).

Society influences development through its social structure (e.g., social inequality and segregation of social strata), age-graded cultural timetables, and social institutions (e.g., educational system and regulations of promotions and retirement) (*see* Age Stratification; Social Stratification). Key contextual contributors to development include the neighborhood or community in which the individual lives, the type of parenting received, and stressful life events such as poverty or sociopolitical upheaval. Similar to biological influences, societal factors also set timetables for development. Individuals of a particular society are exposed to an agreed-upon, age-graded sequencing of major life events. For example, individuals expect to experience significant life events, such as graduating from school or college, marrying, having their first child, and retiring, at certain points in their lives (Heckhausen, 1999). These guidelines are responsible for the common life paths of individuals in a given society as well as age-appropriate behavior, roles, and responsibilities. Finally, social institutions like the education and legal system play a large role in structuring the life course. Minimum age requirements and mandatory retirement laws for certain professions and in certain countries determine when an individual can participate in the labor force. Thus, society and culture structure the opportunities to pursue developmental goals across the life span.

Current conceptualizations of life span psychology emphasize the role of the *individual* as a coproducer of development (Lerner and Busch-Rossnagel, 1981) and active agent of change (Brandtstädter, 1999; Heckhausen, 1999). Thus, individuals are also producers of their own development. Individuals play both an active and passive role in regulating development across the life span (Lerner and Busch-Rossnagel, 1981). For example, *passive* physical characteristics such as being tall or physically attractive can contribute to an individual's popularity and even lead to greater career opportunities and income (Deaton and Arora, 2009). Being an extrovert, which is a fairly innate aspect of one's temperament, can lead to a larger social network and with it, additional opportunities and resources. Individuals *actively* influence their development primarily through the selection and pursuit of developmental goals (Heckhausen, 1999). By choosing to invest in particular developmental paths or life domains over others, individuals optimize the fit between their preferences and the environment. Individuals shape their social ecology through the friends they make, the colleges they choose, and the careers they pursue. They play an active role in optimizing their development by striving to control the environment, seizing opportunities as they become available, learning from others, and exploring new behaviors and their effects.

Thus far, we have described the three influences of development and how they change over the life span. We will now describe three patterns of influence that define development across the life span: history-graded, age-graded, and nonnormative life events (Baltes et al., 1980). These patterns of influence contribute to commonalities among individuals, interindividual differences, and intraindividual change (or plasticity) (Lerner, 1984). History-graded events are experienced by all individuals living at the same time and lead to differences between birth cohorts. They can include environmental or man-made catastrophes such as natural disasters, wars, or economic recessions. Alternatively, history-graded events can encompass the general zeitgeist of the era (e.g., the present state of social institutions and laws, the general quality of health, or the advancement of technology). Age-graded events are universal for members of a given age group and contribute to commonalities experienced across the life span. For example, all members of an age group experience certain biological and maturational milestones such as learning to talk and walk. Similarly, members of an age group experience societal expectations and pressures in the form of developmental tasks (Havighurst, 1948, 1973). Individuals can expect to participate in life tasks depending on their age, such as attending school in childhood and entering the workforce in adolescence or adulthood. Nonnormative life events are idiosyncratic but can exert a powerful influence on development, such as a genetic abnormality. The influences of development and their patterns and layers combine to produce an action field of development. It is only through the interaction of all these influences that we gain a complete understanding of human development across the life span.

Fundamental Theories of Individual Agency in Human Development

The key metatheoretical principles proposed by Baltes (1987) and other early life span developmentalists were broad and open enough to allow the emergence of several developmental models, each with their own theoretical concepts and empirical phenomena (Heckhausen, 2003). Models for specific domains of functioning gave way to broad, process-oriented theories of developmental regulation, the three most prominent of which being selection, optimization, and compensation (SOC) proposed by Paul Baltes and Margaret Baltes and their colleagues (Baltes, 1987, 1997; Baltes and Baltes, 1990); the dual-process model of assimilation and accommodation proposed by Brandtstädter (1989, 2009); and the motivational theory of life span development (MTD) proposed by Heckhausen et al. (2010).

As a group, the theories of life span development aim to describe, explain, predict, and optimize human development across the life span. Similar to developmental systems theories, these theories stress the important role of individuals and dynamic person–context relations in influencing human development. Individuals are able to regulate their development according to opportunities and constraints in their social ecology. They actively seek to adjust the use of developmental regulation strategies to optimize development across the life span.

Selection, Optimization, and Compensation

The SOC Model (Baltes and Baltes, 1990; Baltes et al., 1998; Freund and Baltes, 2002) provides a metatheoretical framework for understanding three processes of developmental regulation across the life span: goal selection, goal pursuit, and goal maintenance. These processes are sustained through the use of SOC strategies. A key aspect of this model is that individuals engage in these processes in a coordinated manner to extract the most from their environments and achieve adaptive developmental outcomes.

Elective selection involves the construction of a goal hierarchy and commitment to a set of goals and preferred activities. Individuals focus on goals that are most important to them for their particular life stage. These goals change throughout the life course according to opportunities and constraints. For example, an older individual may select goals and optimize gains in domains that he or she can excel in, such as volunteering, rather than domains that are no longer possible, such as becoming a world-class athlete. Optimization refers to the investment of resources in the selected activity or goal. For example, pursuing a goal may require acquiring new skills. Compensation occurs when individuals experience a shortcoming, like age-related decline. In these cases, individuals invest more resources and use compensatory strategies to maintain an adaptive level of functioning and achieve their goals. An individual may rely more on culture or redistribute available resources to areas of need. Concert pianist Arthur Rubinstein who still performed at 80 years of age demonstrates all three aspects of SOC in adaptive functioning (Baltes and Baltes, 1990). As he got older, Arthur maintained a high level of performance by selecting fewer pieces to play, practicing these pieces more, and using certain 'tricks' to make up for a decline in motoric speed, such as purposely slowing down before fast and difficult segments. Finally, the SOC model specifies adaptive loss-based selection strategies that individuals use when functional loss has occurred. For example, individuals can adjust current standards and goal hierarchies to facilitate future goal pursuits.

Dual-Process Model of Assimilation and Accommodation

While the SOC model views the fundamental function of developmental regulation as the maximization of gains and minimization of losses, the dual-process model emphasizes the need to preserve self-consistency across the life span (Haase et al., 2013). As an action theory of development, Brandtstädter's (1989, 2009) model postulates the self-concept as the organizing and guiding force behind development. Development is regulated via a self-organizing process to minimize discrepancies between desired and actual goal states. Individuals seek to reduce self-discrepancies and emotional distress through the use of two developmental regulatory processes: assimilation and accommodation.

Assimilation refers to an individual's active and intentional efforts to attain desired developmental goals and outcomes by changing the environment. For example, an individual may strive tenaciously to achieve a valuable goal, such as a successful career or happy family. Assimilation is most adaptive when opportunities to pursue the goal, resources, and goal importance are high. Accommodation, on the other hand, is most adaptive

when resources are scarce and the goal is less important and easily substituted. Accommodation involves subconscious cognitive processes that reduce the discrepancy between the actual and desired goal states. For example, an individual may nonintentionally reappraise his or her actual goal state in a more positive light. Conversely, the individual may also reappraise the desired state as less positive. Accommodation strategies are particularly salient when challenges emerge or goals can no longer be attained. In this case, individuals should use accommodative cognitions to flexibly adjust goals, reevaluate the self, or find meaning in failure.

Assimilation and accommodation processes have the same goal: to reduce discrepancy and distress in the self. However, they operate in opposing ways, such that the use of one process inhibits the other (Brandtstädter and Rothermund, 2002). While assimilative processes emphasize the role of intentionality in forming goals, values, beliefs, and volitions, accommodative processes are mostly beyond conscious awareness.

Motivational Theory of Life Span Development

The MTD is based on the proposition that, throughout life, humans strive to maximize their control of the environment and their own development (Heckhausen et al., 2010). Individuals regulate their development by engaging with appropriate developmental goals and disengaging from goals which have become unproductive. In doing this, individuals make use of the enormous potential for plasticity and change across the life span, as well as take into consideration the age-graded constraints on plasticity (e.g., biological, sociocultural, and age-normative limitations). It is through this interaction between plasticity and constraints that individuals select specific developmental goals to pursue. Individuals select the most adaptive and age-appropriate developmental goals using a higher order self-regulatory process called optimization (Heckhausen, 1999; Heckhausen and Schulz, 1993). The optimization of goal choice, which differs from optimization in the SOC model, is a higher order regulatory strategy that guides individuals' engagement with and disengagement from various developmental goals.

The specific heuristics of the optimization principle help individuals determine the ideal time to pursue a goal, taking into account both the opportunities available to the individual as well as consequences and trade-offs for pursuing one goal over another. For example, goal pursuit is only adaptive if sufficient opportunities in the developmental ecology exist to facilitate its attainment. Thus, goal pursuit should be congruent with age-graded opportunity structures and developmental timetables. Equally important when choosing developmental goals is to consider the broader context and impact of pursuing the goal for overall functioning and long-term development. Pursuing the goal should not negatively impact the attainment of concurrent or future goals. At the same time, the individual should maintain a minimum diversity of goals to guard against developmental dead ends if the goal is not attained or goal pursuit is no longer possible. Thus, these heuristics work together to support goal engagement as opportunities in the environment arise, and goal disengagement as opportunities fade away. For example, a woman of childbearing age who wishes to have a child should pursue this goal when the biological opportunities to do so are favorable. In addition, she should consider the consequences of having a child on other important domains, such as career, and keep in mind that investing too heavily in any one domain may have negative consequences for long-term development (Heckhausen et al., 2001).

The action-phase model of development proposed by Heckhausen (1999) outlines the motivational and self-regulatory strategies used to regulate development throughout the life span, as it is organized into cycles of goal selection, goal engagement, and goal disengagement. These processes are especially important when challenges and difficulties arise in goal pursuit. Goal engagement involves various control strategies that augment an individual's behavioral and motivational resources. Behavioral resources include the investment of effort, time, strategies, and persistence in attaining the goal. Individuals can also seek out additional external sources of support if needed. Motivational resources involve the level of commitment and importance tied to the goal as well as the ability to stay focused on the goal despite attractive alternatives. If the goal has a deadline, such as the 'biological clock' of childbearing for women, the opportunities to successfully attain the goal decrease with time, creating a sense of urgency (Heckhausen et al., 2001). Thus, individuals increase the intensity of striving for the goal as the deadline nears since there is only a limited amount of time to attain the goal. Indeed, research shows that individuals who tailor their control striving to the controllability of outcomes and engage with goals when control opportunities are plentiful, as well as disengage from goals when controllability is low, achieve better developmental outcomes, enjoy better psychological and physical health, and live longer lives (e.g., Hall et al., 2010; Heckhausen et al., 2001; Wrosch and Heckhausen, 1999; Wrosch et al., 2007).

Goal disengagement occurs when the goal is no longer attainable; either the goal has been successfully completed or it can no longer be pursued for a number of reasons. For example, the developmental deadline may have passed. In this case, whether or not the goal state was reached, it is adaptive to disengage from the goal. If the goal was successfully met, the individual can begin a new goal cycle of selection and engagement. If the goal was not attained, individuals may choose to adjust the goal or pursue another goal altogether. Compensatory strategies associated with goal disengagement work to protect motivational resources and self-esteem after failure so the individual can continue to pursue new goals. Individuals who continue to pursue goals after they are no longer attainable have worse mental and physical health than those who disengage from the goal. This relationship holds for goals in various domains, such as childbearing, romantic relationships, and health (Heckhausen et al., 2001; Wrosch and Heckhausen, 1999; Wrosch et al., 2002).

Altogether, it is through these various control strivings that individuals optimize goal pursuit and their development. Individuals differ in the degree to which they adjust their goal engagement and disengagement to changing opportunities in the environment. Those who use adaptive strategies at appropriate times as well as transition quickly and effortlessly to different phases in the action cycle will attain better developmental outcomes and optimize their mental and physical health.

Methods

What has set the field of life span psychology apart from other subdisciplines of psychology is its emphasis on developmental change across the life span. Only by following individuals and their interactions with the environment over time is it possible to discern patterns of change. The most important research design to test propositions of life span theories is a longitudinal design (*see* Longitudinal Data). This type of study allows researchers to capture real-life processes that unravel over the course of the individual's life. Longitudinal studies assess interindividual patterns of intraindividual change, while cross-sectional studies are limited to interindividual differences and cannot address age-related change. Ideally, longitudinal studies are prospective in nature with a large and representative sample to sufficiently track developmental change. Multiple cohorts of participants can be added, as in cross-sequential designs, to help rule out confounding cohort effects.

Several important developmental phenomena can be assessed with longitudinal studies. One is the study of life transitions, such as entering or exiting the workforce. Studying life events is important because as particularly stressful periods in one's life, they have the potential to set individuals on different developmental trajectories. For any life event, there is heterogeneity in reactions that vary across different domains of functioning. People change in different directions and at different rates. Since data are collected across a span of years or decades, researchers can disentangle the impact of earlier life events and conditions on later developmental outcomes, such as health and well-being. Even if the event is a nonnormative one, such as acquiring a chronic disease, a prospective study will guarantee that a subset of individuals experience the life event if the sample is sufficiently large and representative.

Although longitudinal designs are necessary to study developmental change (see Propensity Scoring), they need to be combined with the most up-to-date methods of analysis (*see* Life Course and Event History Analysis). Analyses must go above and beyond average levels of change (i.e., between-person differences) to produce information about individual levels of change. One current method of analyses is multiphase growth curves (see Growth Curve Analysis; Statistical Analysis: Multilevel Methods). These models capture responses to life events, but also account for individual difference characteristics and risk or protective factors that were collected at earlier assessments (Gerstorf et al., 2010; McArdle and Nesselroade, 2003; Ram and Grimm, 2007; Singer and Willett, 2003). Thus, researchers are able to uncover the psychological and biological mechanisms underlying differential levels of change and development. Researchers can also investigate the cumulative effects of these variables and their influence on successful development.

In combination with longitudinal designs, propensity score matching can be used to increase our understanding of developmental change. Propensity score matching simulates an experimental design by investigating important covariates and matching participants on these variables to create a 'control' group and a 'treatment' group. Propensity scores of each group can then be used in a logistic regression to examine the differential likelihood of outcomes by group (i.e., whether or not the individual experienced a particular life event) (Stuart, 2010; Thoemmes and Kim, 2011). This methodology allows for more confident causal statements than traditional quasiexperimental designs. Finally, longitudinal design would benefit from including a microlongitudinal study or 'measurement burst' within the larger study. An intense series of measurement points can reveal the underlying mechanisms and processes associated with developmental change, such as how day-to-day events influence long-term outcomes (Infurna et al., under review).

Additional methodologies are useful in understanding the basic processes involved in plasticity, or the ability to change throughout the life span. For example, the plasticity of cognitive decline is assessed with a testing-the-limits experimental paradigm (Kliegl and Baltes, 1987). This type of short-term longitudinal study typically uses training in an effort to reverse cognitive decline among older individuals. The baseline capacity of individuals without training reveals everyday differences in cognitive functioning. Baseline reserve capacity refers to performance on tasks when conditions for learning are optimized, but no training has occurred. Finally, developmental reserve capacity refers to individuals' maximum performance attained with extensive training that has elevated performance to an asymptote. The potential for plasticity can be seen if baseline reserve and developmental reserve capacities are greater than baseline capacities.

Areas for Future Research and Conclusions

As a still emerging field in psychology, life span psychology has a bright and interdisciplinary future. Three similar, yet distinct, theories currently dominate the field of life span psychology: the SOC model, the dual-process model, and the MTD. Because the theories are conceptually and functionally similar, Haase et al. (2013) proposed a theoretical and empirical integration: a unified theory of life span development with three central processes of adaptive developmental regulation: goal engagement, goal disengagement, and metaregulation. The SOC model and the dual-process model both contain constructs similar to goal engagement and disengagement, as proposed by the MTD. Goal engagement is similar to Brandtstädter's (1989) assimilation and the SOC model's elective selection, while goal disengagement is similar to Brandtstädter's (1989) accommodation and the SOC model's loss-based selection. The MTD is the only theory that recognizes a higher order developmental regulation process: optimization. More research is needed on the validity of the optimization construct within varying contexts and populations. By its nature, optimization is difficult to assess via self-report measures and would benefit from a combination of scale-based and open-formatted interviews.

Theories of life span development share the goal of using regulation strategies to optimize development across the life span. However, current theories disagree on what should be the ultimate criteria of successful or adaptive development (Heckhausen, 2003). The dual-process model does not operationalize successful development, making empirical tests of the model difficult. The SOC model gives several definitions of adaptiveness in developmental regulation, such as the maximization of gains and the minimization of losses or attaining desired outcomes and avoiding undesired outcomes, which value both subjective and objective indicators of success

(Baltes, 1997). While subjective criteria incorporate the personal goals and cultural context of individuals, they are also subject to rationalization biases and the possibility that an individual may accomplish little by objective standards but be highly satisfied. Although the SOC model argues against a universal criterion of adaptive development, there is a general consensus regarding what it means to be successful in different cultures. That is, high levels of functioning are desired in cognitive and intellectual performance, physical mobility (or absence of disability), affective functioning, and social relations (Heckhausen, 2003). The criterion for successful development in the MTD is to maximize the control potential of the individual in valued domains across cultures. In moving forward, the field would benefit from adopting criteria for successful development that is explicit, nonrelativistic, and objectifiable.

The majority of research in life span development gathers data through self-report measures. This type of assessment works well when investigating the explicit and effortful intentional processes of goal engagement and disengagement, but falls short in measuring processes that are beyond conscious awareness. Intentional processes are those that deliberately manipulate volitional commitment, such as making the decision to disengage from a goal. There are several problems inherent in self-report measures, such as the possibility of selective and biased informational processing and recall (Brandtstädter, 2000). Conversly, subintentional processes include various secondary control processes designed to cope with loss and protect resources. Examples include shifting priorities or increasing cognitions that avert self-blame. One of the ways these processes are measured is through an incidental memory paradigm (Heckhausen et al., 2001). Because secondary control processes are associated with well-being and adaptive development, it is important to accurately tap into their subintentional nature with measures that go beyond self-report.

According to the MTD, discrete and radical shifts between goal selection, goal engagement, and goal disengagement are most adaptive, but more research is needed to confirm this hypothesis (Heckhausen et al., 2010). It is not clear which specific processes are involved when individuals transition from one phase of the action-phase model to another. In the real world, there is much variability in how people transition and this may have important consequences for long-term developmental outcomes.

Finally, additional research is needed to investigate the interaction between biological and sociocultural constraints and individual characteristics. Elias (1969) described a dynamic relationship between societal regulation of behavior and individual regulation of behavior. As one increases the other decreases, so when societal constraints are few or nonspecific, the individual must invest more in regulating his or her development by seeking to control the environment. And conversely, when societal constraints are more severe, the individual does not need to internalize rules and norms. This way, a not-too-much-and-not-too-little level of regulatory constraint is maintained across societal change. In the context of ubiquitous international migration, individuals need to adjust their life span-regulatory striving when migrating between countries with different levels of constraints in social mobility.

At its core, development proceeds as a transaction between the individual and his or her social ecology. Theories of life span developmental psychology showcase the impressive ability of individuals to optimize their development across the life span. As coproducers of development, individuals construct an action field that takes into account changing life opportunities and constraints in biology and society to select the most adaptive developmental goals. They maximize the likelihood of goal attainment through motivational and self-regulatory strategies, and use additional strategies to adjust for setbacks or compensate for age-related declines in functioning. The potential for developmental change and plasticity across the life span is great.

This article is a revision of the previous edition article by H. Keller, volume 13, pp. 8840–8844, © 2001, Elsevier Ltd.

Abstract

From an evolutionary perspective, reproductive success can be understood as the driving force for specific developmental pathways, which present coherent answers to contextual demands. The sequence and structure of developmental stages across the life span constitute reproductive styles that promise best inclusive fitness within the respective context. Although the prolongation of the life span in humans compared with all others species is certainly a result of selective forces, senescence, i.e., biological aging, seems not to be shaped by natural selection, but rather a by-product of earlier neutral or beneficial gene expression.

Evolutionary Assumptions

Evolutionary theorizing considers striving for optimal reproductive success as the ultimate goal, also, of human development. This assumption specifies that not only the proximate regulation of physical and biological systems, but also the social behavior and complex psychology of human beings follow a reproductive logic. Reproductive success is expressed in terms of inclusive fitness, which comprises the individual's own procreation (Darwinian fitness) and the procreation of relatives with whom the individual shares genes (indirect fitness), thus establishing the principle of kin selection (Hamilton, 1964). Therefore, the evolutionary perspective focuses on the gene as a unit of analysis. However, "… it is not the naked gene, that is exposed to selective forces directly" (Mayr, 1994: p. 206), but rather the "realized animal, that lives or dies, breeds or helps the relatives" (Daly and Wilson, 1983: p. 32). Although individuals are considered as 'vehicles' of their genes (Dawkins, 1976), the importance of the phenotypical individual for determining reproductive success has recently been (re)emphasized (Laland et al., 2000).

However, this position has been challenged since some time, claiming that the group selection is also favored from an evolutionary perspective. In an article in Brain and Behavioral and Brain Science (2014), Smaldino argues that the level of group organization has to be taken into consideration since properties of particular human groups may represent evolutionary advantages over other human groups.

According to Smaldino's (2014) group-level traits, as characterized by the structured organization of differentiated individuals, represent a mode of selection that is different from traditional group selection approaches (multilevel selection theory). The implied focus on cooperative group activities (compared to a focus on competition that is implied by the assumption that genes drive selfish interests (genetic egoism perspective)) is compatible with the cooperative nature and the shared intentionality in social actions that very young human infants already display, e.g., emphasized by Michael Tomasello (1999) (for a critique of this group selectionist approach see Pinker, 2012, in his Edge essay, The false allure of group selection, http://edge.org/conversation/the-false-allure-of-group-selection) and the interesting comments by leading scholars in the field (the reality club). It will be a matter of empirical proofs to test hypotheses from these competing theoretical points of view.

It is, however, commonsense that it is not the adult individual who represents the product of evolution; rather, the whole life span with the different developmental phases is shaped by selective forces with the eventual exception of senescence, which itself seems not to be a product of selection. Aging is a concomitant of sexually reproducing individuals. The inevitability of death due to environmental stressors during human history has resulted in a decrease of individuals with increasing age, so that the power of natural selection also decreased (Medawar, 1952).

Life history theory (Alexander, 1990) regards the developmental course of the individual life span as the result of a trade-off between investment into one's own growth and development (somatic effort) and the investment into reproduction, comprising the functional systems of mating and parenting (reproductive effort; Chisholm, 1996). Somatic efforts accumulate reproductive potential whereas reproductive efforts decrease the residual reproductive value. Evolution has thus shaped humans into reproductive strategists who constantly have to make 'decisions' about the best allocation of investment (Voland, 1998; Shenk, 2011). The heuristics of reproduction are contingent upon environmental demands, which comprise material and ecological forces as well as social complexity (see Dunbar, 1996). Especially, the evolution of intelligence as a necessary prerequisite for exploring environmental resources and regulating the social behavior of expanding groups favored learning as a second asset of adaptation. Yet learning is not random, but follows (genetically imposed) biases and constraints ('central tendencies,' MacDonald, 1997; 'epigenetic rules,' Lumsden and Wilson, 1981) to acquiring specific environmental information during specific phases of development allowing easy learning at these points in time (Boyd and Richerson, 1985).

Psychological development across the life span can simultaneously be interpreted as a structured sequence of developmental tasks in order to improve social and cognitive skills as well as the formation of a reproductive style. Evolutionary socialization models have described the ontogeny of individuals' reproductive styles as a meaningful passage through the

developmental tasks of childhood and adolescence. In particular, the resource situation and family climate during early childhood are considered to be predictive of attachment formation. The quality of attachment in turn influences psychological adjustment during late childhood. Psychological development also influences neurophysiological and maturational processes, leading to the somatic consequences of defining the beginning of puberty. The beginning of puberty channels the reproductive style; especially with regard to the age at which first giving birth, the spacing, and number of children with the respective implications for parental investment (Belsky et al., 1991; Keller, 2007, 1996). Empirical studies from different parts of the world have supported the view of different developmental trajectories as specified by these models (Keller and Kärtner, 2013). The new perspective of evolutionary theorizing is thus the assumption that neurophysiological and psychological regulations of behavioral development (proximate causes) are influenced by adaptive, i.e., shaped through the history of humankind, mechanisms that serve the ultimate function of optimizing reproductive success. The postreproductive phase is therefore not subject to the same degree of selection pressure as the prereproductive and reproductive life phases (Baltes, 1997; Geary and Bjorklund, 2000). Accordingly, old age is not a distinct phase in stage conceptualizations of the life history approach (Bogin, 1997).

It also remains an open debate in evolutionary approaches, which are the principles that guide these trade-offs. Especially, discussions about the morality of humans and conscience raise questions about the prevalence of a trade-off concerning reproduction or a genuine social orientation (Voland, 1998).

In the following sections, the functional significance of the different developmental phases for reproductive success will be analyzed. The developmental phases of infancy, childhood, adolescence, adulthood, and old age will be briefly characterized with respect to their possible evolutionary roots. Old age is included in this analysis, since the assumption of structural continuity implies that earlier experiences shape later ones, so that the quality of old age could be regarded as a consequence of the earlier reproductive life (Keller, 1991).

Developmental Phases across Life Span

Infancy

The extreme helplessness ('altriciality') of the human newborn can be considered as part of a reproductive strategy to becoming a better adult ('better adult hypothesis,' Alexander, 1990), since it allows the baby to invest all available resources in growth and development. This view is in contrast with the common interpretation of infants' helplessness as a consequence of a physiological preterm birth, due to hominid brain growth (Prechtl, 1984). Early development is shaped by the investment that parents allocate to each child individually, depending on their own and the child's reproductive values (e.g., age of parent, social support, sex, and birth position of child). Early experiences form the basis of the psychological adaptation to the respective physical and social environment in prompting phenotypic development. Accordingly, infants adopt internal representations of social relationships (*see* Integrated Attachment Theory; Attachment during Infancy and Early Childhood: Cultural Variations, Development of) and a primary conception of the self, focusing on the expectations of reciprocity as the balance of give and take that can be expected in future social relationships.

Childhood

At about 2 years of age, a developmental transition with a new focus on the extension of the physical and social range of children's activities can be observed in many cultural contexts. This marks the beginning of children's apprenticeship that involves the adoption of promising strategies for acquiring resources in their particular environment. Mediated through the culturally primed beliefs and values ('ethnotheories') of their social environmental and social competence through participatory learning as well as by adopting and creating developmental niches ('niche picking'), which include the implicit and explicit reflection of sex differences as concomitants of adult reproductive life.

Adolescence

Adolescence constitutes the transition from childhood to adulthood. The beginning of adolescence is universally defined by entry into puberty. The duration of adolescence, however, differs substantially across cultures, varying from transitional rituals during a few weeks to a stage that last several years, depending mainly on economic constraints and educational provisions (see Schlegel and Barry, 1991). The attainment of sexual maturity is a biological marker variable with a hereditary component and is contingent upon ecological factors, such as nutritional status and physical condition, as well as previous socialization experiences, especially the security and stability of the early home environment. At the same time, this marker variable is believed to be predictive of future reproductive decisions (e.g., age at first sexual intercourse and at first childbirth, duration of interbirth intervals). Although similar developmental trajectories for males and females have been empirically identified, sex-specific reproductive strategies with their respective costs make it likely that the environmental factors influence female fecundity more strongly than male. Therefore, and owing to the greater accessibility of menarche as an empirical measure, female developmental trajectories are overrepresented in the literature. Psychosocial stress in the family of origin, especially marital conflict and father's absence, has been documented as decreasing the age of menarche in different contextual systems. Particularly, the divorce of parents during a child's first 5 years of life could reliably be related to early menarche (Chasiotis et al., 1998). The perception of this environmental scenario may support the development of a more quantitative-oriented reproductive style with lesser parental investment whereas marital stability could be considered as part of a qualitative style with higher maternal and paternal investment. Thus, low-ecological stress (i.e., good nutritional status and a balanced physical condition) as well as high-psychosocial stress (e.g., divorce of parents before the age of 5 years) can result in earlier maturation, whereas high-ecological stress and/or low-psychosocial stress can lead to later maturation. There is also

evidence that prenatal factors influence the age of menarche, e.g., being born smaller accelerates menarche (Gluckman and Hanson, 2006). The main reproductive function of the variability of sexual maturity is to reduce the costs of premature reproduction. If an individual 'waits' for sexual maturity, the resources can be allocated to growth, which will increase the reproductive value at maturity. On the other hand, the delay might increase the probability of surviving until the reproductive age (Charnov, 1989).

The onset of reproduction varies with the duration of adolescence across cultural contexts. Especially in traditional rural societies, reproduction begins soon after sexual maturity and seems to be more quantitatively oriented, whereas reproduction in urban-educated societies is delayed until individuals complete education and seems to be more qualitatively oriented. It is a novel phenomenon that there is a mismatch in timing between the age of menarche (earlier) and the achievement of psychosocial maturity (later) (Gluckman and Hanson, 2006). This mismatch may be indicative of another sign of separation between genetic and cultural evolution, which poses further challenges to the understanding of the evolutionary bases of behavioral development.

Adulthood

In evolutionary terms, adulthood is the phase of reproduction with the task to resolve various allocation conflicts. First, the conflict between current and future reproduction (i.e., investment in growth or reproduction) has to be addressed, culminating in the decision of when to start reproduction, and the related issue of nepotistic effort, i.e., investing in one's own offspring or temporarily (or even permanently) adopting the role of a 'helper in the nest' (Voland, 1998). The second allocation conflict concerns the question of investment in quality or quantity of offsprings, which determines the number and spacing of children. Since these decisions not only have to be made generally as an expression of reproductive style, but also individually for each offspring separately, parent–child conflict is an inevitable consequence (Trivers, 1974). Survival and psychological adaptation are facilitated when not only maternal, but also paternal investment is spent on the infant. It is assumed that partner bonding and family cohesion evolved as psychological mechanisms to facilitate the development of 'better adults.' This view seems to confirm the relationship between father's absence and (increased) infant mortality in traditional societies, e.g., among the Ache Indians in South America (Hill and Hurtado, 1996).

The determinants of reproductive success differ for males and females. Females per se make a higher investment owing to intrauterine pregnancy and nursing, supporting a qualitative parenting style with higher investment in fewer offspring. They have to decide whether they want to continue to look for a better mate or start reproducing. The prototypical male strategy, on the other hand, should be more quantitative, that is, to invest less in more offspring, due mainly to the fact that it is difficult for a male to know precisely whether he is the father of an infant ('paternity insecurity'). Moreover, males show greater variability in their reproductive rates, from having no children to having many children. Men have to decide between the 'cad versus dad' strategies, i.e., maximizing fertilization or parental investment (Voland, 1998). The trade-off that individuals have to accept therefore entails the balance of mating and parenting efforts. Studies of partner selection have documented nevertheless universal preferences for the two sexes: females prefer partners with characteristics indicative of economic success, whereas males prefer females with characteristics that indicate reproductive capacity (youth, health). In addition, there is preference by both males and females for mates who are similar to themselves in a variety of characteristics ('assortative mating,' Wolf and Figueredo, 2011). Parental investment constitutes the intergenerational link through which the offspring experiences the socialization style that the parents have developed as a result of their own past as well as current experiences. In the case of human beings, not only time and energy as parameters of investment decisions have to be taken into consideration, but also the psychology of the phenotypic adult (Keller, 2000).

Old Age

Old age covers the postgenerative phase of the life span. Yet, it has been proven meaningful to differentiate a third young-old age span form about 60–75 years where the vital capacity has improved to compensate for about 5 years due to cultural evolution, from a fourth age span from around 80 to 100 years (cf Baltes, 1997), which has emerged due to increasing life expectancy, but where senescence has predominantly detrimental effects. These might originate as by-products from possibly two processes: (1) selective neutrality of the genome with no effect at early life and deleterious effects at later life and (2) antagonistic pleiotropic gene action that supports reproductive success during the reproductive life stages (Martin et al., 1996). One detrimental factor that has been identified across species may be metabolic oxidative damage operating in macromolecules. On the other hand, it has been argued that the extension of the life span serves individual fitness by supporting the development of the child's and grandchild's generation (Johow and Voland, 2013). Although this 'grandmother' hypothesis (Peccei, 1995) is controversial, researchers nevertheless report that being a grandparent increases life satisfaction in old age. The physical deterioration especially of the oldest-old age requires extrasocietal cultural resources, which at the same time become more difficult to be exploited effectively. Accordingly, the regulation and compensation of losses become a major mechanism for ontogenetic processes (Baltes, 1991). Relating interindividual differences in regulatory competencies to the earlier reproductive life histories might be a challenge for life span psychology.

Outlook

Although essential questions such as the interplay of genetic and social influences on phenotypic development remain largely open, the evolutionary view on the human life span offers a stimulating perspective on many controversial issues of psychological development, e.g., the nature of sex differences or the normative character of secure attachment relationships. During their ontogenetic development, individuals, based on

universal genetic programs (e.g., for language acquisition, partner preferences, parenting styles), acquire the contextually relevant ecological, social and cultural information (e.g., mortality rate of their population, economic constraints, cultural values) both intentionally and intuitively to promote their psychological development so that it is adaptive for the reproductive style that promises best inclusive fitness in the given situation. Old age challenges the cultural nature of humans in a very special way, since trade-offs are no longer associated with epigenetic rules or central tendencies. Humans therefore have to use the accumulated knowledge of the previous life stages in order to redefine and redirect the allocation of resources and balance universally evolved behavioral heuristics, ontogenetically acquired styles, and situational regulations, making each life history unique. The question of assumed ultimate causes, "how do these behavioral regulations or these motivational systems contribute to reproductive success," might allow us to reframe empirical findings and adapt research designs accordingly. Evolutionary approaches face many challenges due to rapidly changing environments and the concomitant separation of genetic and cultural evolution. The declining fertility with increasing resources is such a challenge (see Mace, 2000). For the future discourses, multidisciplinary perspectives will be crucial.

Life-style, History of the Concept

Johanna Muckenhuber, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term lifestyle is widely used in sociology and many other subdisciplines of the social sciences. Alfred Adler and Max Weber can be named as the first who developed the term and the concept.

Lifestyle can be defined as a set of behaviors, preferences, and practices, which are present in daily life.

In modern social theory, Beck and Bourdieu further developed the concept from an agency perspective (Beck) and from a more structural perspective (Bourdieu).

The term lifestyle is used in many empirical studies in different subdisciplines of the social sciences, but in a very broad way, in many cases without reference to the underlying theoretical assumptions.

The term lifestyle gained importance during the last decades. Having its origins in sociological and psychological theory, it was further developed, operationalized, included in empirical research, and finally distributed to many different disciplines. The aim of this article is to describe the origins of the term lifestyle and to describe how it is used in different disciplines of the social and behavioral sciences, sociology, health sciences, and leisure studies, in particular.

Definition

The concept of lifestyle was developed first by the German sociologist Max Weber (see Weber, 1968, 1972) and by the Austrian psychologist and psychoanalyst Alfred Adler (see Adler, 1924, 1933).

The Oxford English Dictionary (OED) (OED, 2014) offers several definitions of lifestyle. According to it lifestyle in general today can be defined as "a style or way of living (associated with an individual person, a society, etc.); esp. the characteristic manner in which a person lives (or chooses to live) his or her life." In Adlerian psychology, it is "a pattern of reactions and behavior that is established in childhood and remains characteristic of an individual" (OED, 2014). In addition, the OED refers to compounds of lifestyle "relating to the way in which one lives (or chooses to live) one's life, esp. with regard to quality of life, as lifestyle advice, lifestyle change, lifestyle factor, lifestyle group, lifestyle option, etc." and in the specific case of marketing "relating to a publication, a product, advertising, etc., which is designed to appeal to consumers by association with a lifestyle regarded as desirable, glamorous, or attractive, as lifestyle advertising, lifestyle brand, lifestyle magazine, lifestyle marketing, etc." Finally in related to health, OED refers to lifestyle as "lifestyle drug n. a drug prescribed to treat a condition that is not necessarily serious or life-threatening but that has a significant impact on the quality of life" (OED, 2014).

The term lifestyle was and is used in different ways. One important aspect of differentiation is the actor who is addressed. Some authors refer to individuals with a certain lifestyle, some authors refer to groups of persons (which are at least partly stable over time), and other authors refer to a certain class and its lifestyle. The class is not a group with individuals who know each other. Individuals of the class have a set of properties in common (see Ansbacher, 1967: p. 11).

The individual lifestyle is defined as a kind of stable characteristics and even more, most actions of the individuals are interpreted as to fit in a relatively consistent manner to their lifestyle.

The definition of the group lifestyle differs according to the authors. Some authors refer to the dynamics and specific constellations of a group when writing about group lifestyle. Others like Parsons (see Parsons and Bales, 1955) refer more to classificatory systems. Parsons, for example, argues that the husbands' and fathers' occupation is central in determining the lifestyle and in this context the status of a family.

Concepts of lifestyle, which belong to a certain class, are often used to describe and to analyze status groups and occupational groups, but cultures and subcultures as well. Thereby they refer to the concept of class but go beyond class. Max Weber was one of the sociologists who used the term lifestyle in this way. In addition, these definitions can be found in more recent theories. In this article, they are discussed in the context of sociological theory and research and in the context of the use of the term lifestyle in other disciplines later on.

Lifestyle by Alfred Adler

Alfred Adler as psychologist and psychoanalyst focused on the individual dimension of lifestyle. He argued that individuals' actions are purposive, goal directed, throughout consistent, and unique for each individual. Therefore following Adler, all actions are ultimately subjectively determined.

Beginning with 1926, Adler started to use the term style of life. In 1929, he officially abandoned the term life plan to use lifestyle instead (see Ansbacher, 1967). In the development of the concept, Adler seems to be influenced by Folkert Wilken who worked together with him. According to Ansbacher, Adler describes lifestyle as follows: "In considering the structure of a personality, the chief difficulty is that its unity, its particular style of life and goal, is not built upon objective reality, but upon the subjective view the individual takes of the facts of life" (Ansbacher, 1956). But,

nevertheless, pointing out the importance of the concept of unity, Adler argued that it is also important to take into consideration the context of the individuals when analyzing their lifestyle.

Following Adler, the lifestyle develops in the first years of the life of a child. Adler pointed out the importance of early childhood. He argues that the particular style of life even of a child "is not built upon objective reality, but upon the subjective view the individual takes upon the facts of life" (Adler in Ansbacher, 1967: p. 191).

Adler as a psychotherapist was mainly concerned with personality change. According to him, psychotherapy needs to investigate the patient's "present field of action and then proceed to his general movement through life, to his lifestyle" (Dreikurs, 1961: p. 89). In this context, he writes about the life plan, which guides the persons through their life. The life plan covers the idea of a goal in each individual's life and the idea of a coherence of all partial movements during the life course (Adler, 1924: p. 4). Adler was very close to some modern sociological theories when writing that everybody has a kind of subconscious idea about himself, what he or she should do in, and with his/her life without really understanding and knowing what this is (Adler, 1933).

But it was Max Weber who developed the concept of lifestyle in sociology, more or less at the same point in time as Alfred Adler developed his concept.

Lifestyle and 'Lebensführung' by Max Weber

Max Weber in contrast to Adler focused on a collective dimension of lifestyle. He differentiated between 'Lebensführung,' 'Lebenschancen,' and 'Lebensstil.' 'Lebensführung' can be literally translated as life conduct and refers to choice and self-direction in a person's behavior. Therefore, according to Weber, life conduct is an element of choice within his overall concept of lifestyles. The second basic component of the lifestyle is life chances (Lebenschancen), which deal with aspects that cannot be changed voluntarily by the persons. Life chances therefore cover the idea of the importance of structure for agency. These life chances include the probability that a person can realize his or her choices in life and the importance the economic situation of the individuals have on their life conduct. Weber pointed out that "the possibility of status-specific life conduct is of course in part economically conditioned" ("Denn die Möglichkeit, ständischer Lebensführung pflegt naturgemäss ökonomisch mitbedingt zu sein") (Weber, 1972: p. 537). 'Lebensstil' combines both Lebensführung and Lebenschancen. In the process of translation to English, the term 'Lebensführung' and the term 'Lebensstil' were mistranslated according to Abel and Cockerham (Abel and Cockerham, 1993) because both were translated with the same English term 'lifestyle.'

According to Ansbacher, Max Weber used the term lifestyle before Adler. Weber referred to a collective phenomenon and its meaning was quite similar to that of subculture (Ansbacher, 1967: p. 196). Differences in lifestyles are mainly explained by educational differences and Weber points out, that also the status of a person is expressed by a specific style of life (see Weber, 1968).

Lifestyle in the Social Sciences

Sociological Theory and the Concept of Lifestyle

In sociology, the concept of lifestyle is associated with the description of groups, subcultures, occupational or educational groups, and is mostly related to a certain status of a group.

In sociology, the concept of lifestyle is argued to be closely related to the position of the individuals in the sociostructural environment like the economic resources and the level of education.

Thorstein Veblen can be cited as an American sociologist who developed a concept of the lifestyle in the late-nineteenth century. In his theory of the leisure class, he develops the idea that individuals who belong to the upper class do not only own their riches, but that for them it is also important to show their wealth. Veblen develops the idea of a kind of conspicuous consumption. He argued that this conspicuous consumption is important for the upper class in order to keep their status (Bögenhold, 2003; Veblen, 1899). It has been argued that in modern societies this kind of consumption and demonstration of the wealth has changed. Partly this can be refuted, for example, when regarding the ostentatious demonstration of wealth in yachts. But in other aspects, such a change can be observed where wealth is not easily identifiable for everybody but when hidden symbols identify wealth and the belonging to the subgroup of the wealthy just for those who know about these symbols. This knowledge about the symbols of distinction is closely related to Pierre Bourdieu's idea of distinction. Veblen as well as Bourdieu follows the idea that the economic class is strongly related to certain practices and sets of preferences, which constitute the lifestyle of subgroups (Trigg, 2001).

Modern sociological approaches to lifestyle can be separated into those who argue that class and position in social structure are important factors determining individuals' lifestyles, and individualistic approaches who deny the role of class and structural influences.

Pierre Bourdieu is one of the authors who points out the importance of class and social structure. In Bourdieu's theory about social inequality, the concept of lifestyle is closely related to his concept of the habitus. Bourdieu's interest was to develop a theory, which builds a link between structuralism and the main ideas of agency theory. He argued against the dichotomy of both. His concept of the habitus is seen as a missing link, which can explain the pathways how social structure influences human agency. Bourdieu argues that individuals do not dispose of different amounts of economic capital, which can be measured in terms of monetary income and economic possessions but, that persons also dispose of social and cultural capital. Social capital is defined as the "the aggregate of the actual or potential resources an individual has access to" (Bourdieu, 2005: p. 51). These resources depend on the belonging to certain groups. They can be based on material or symbolic exchange relationships and can be more or less institutionalized. In other words, the resources can be based on subjective feelings like recognition, respect, and friendship, or on institutionalized guaranties like legal claims (Bourdieu, 2005: 1:63ff). When writing about cultural capital, Bourdieu refers to the individuals' level of education but also to the knowledge of individuals about cultural and intellectual traditions. This knowledge is crucial in order to develop practices

and to behave in a way, which fits to the class they belong to and, which fits the expectations linked to their position in the social field. According to Bourdieu, individuals are situated in a social field, which is strongly influenced by their economic, social, and cultural capital. This position in the social field has a strong influence on the habitus of a person. The habitus in turn produces a certain lifestyle. Its manifestations can be seen in certain cultural practices (Fuchs-Heinritz et al., 1994: p. 394). These cultural practices comprise, for example, what the persons read, their food preferences, their furnishing, and their preferences for music styles etc. Therefore following Bourdieu the lifestyle is a very important category of distinction in the social interplay between individuals and groups.

Ulrich Beck follows an approach quite different to Bourdieu's theory. Beck is a representative of the individualization theory. He argues that in developed societies we can find rising levels of income, education, social security, and mobility. As a consequence individuals can dispose of more resources than in former times. This in turn leads to a broader and still broadening range of opportunities of individual action. According to this theory, life can be shaped and organized more and more by the individuals. This has two consequences. On the one hand, the persons have more freedom to make decisions and on the other hand, they have the pressure to decide for their own lives with consequences for their present and their future opportunities. Therefore theorists of individualization argue that individuals nowadays feel more anxieties to fail. According to Beck and others, one of the consequences of this situation is that individuals do not develop more and more different forms and styles of life, but in contrast they orient themselves toward similar subgroups and adopt lifestyles, norms, and values of these groups to a large extent. Summing up, it can be stated that following theories of individualization, lifestyles can be chosen by the individuals and are not determined by the position in the social structure, but the choice of a certain lifestyle is influenced by the personality and the subgroup a person belongs to and wants to belong to (Hradil and Spellerberg, 2011).

When comparing structuralist theories like Bourdieu's with his concept of the habitus and theories following the concept of individualization, it is obvious that they differ in some important aspects and lead to different assumptions regarding modern lifestyles (Hradil and Spellerberg, 2011).

1. While Beck's theory of individualization assumes conscious decisions for certain lifestyles, Bourdieu's theory of the habitus assumes more unconscious processes, which have specific practices and lifestyles as a consequence.
2. Theories of individualization assume that lifestyles are a matter of choice and these choices are influenced mainly by individual preferences. In contrast, Bourdieu's theory assumes that the habitus and with this the lifestyle is determined (or if not determined so influenced to a great extent) by material resources an individual disposes of.
3. When following theories of individualization lifestyles should get more diverse over the time, they should be independent from class and social structure, and should be changeable. More structuralist theories, like Bourdieu's, lead to the assumption of relatively stable lifestyles, which differentiate between individuals according to their position in the social structure.

Both theoretical currents have many followers. But empirical findings are as diverse and ambiguous as the theories are. Therefore no decision in favor of one of the two theories can be taken.

Lifestyle in Different Disciplines of the Social Sciences

In different disciplines of the social sciences, the concept of lifestyle gained importance in the last decades and still gains importance. As it is not possible to give an overview on the use of the term lifestyle in all disciplines of the social sciences in the following paragraphs, it will be depicted exemplarily for health sciences and for the field of leisure studies.

In Health Sciences

In health sciences, the term lifestyle has been used for some decades now. In particular, public health studies and applied sciences in health promotion use the concept. In contrast to most sociological research, many studies in health sciences are strongly empirically oriented. Regarding the theoretical background there is a split in health sciences. Some research in social medicine assumes that social structure strongly influences health behavior and health. This research shows and showed that the socioeconomic status of a person (SES) is an important determinant of health. Other research refers to agency theories and points out the capacity of individuals to choose their behavior. Lifestyles relevant for health comprehend behavior like smoking habits, diet, exercise, alcohol consumption, etc. These lifestyles can either be seen as a consequence of structural conditions or as a consequence of rational choice. Past health research focused on biological and psychosomatic as well as structural explanations for health. But in late modernity, health has been interpreted more and more as an achievement, which can be reached by the individuals when following certain rules of behavior, when adopting a healthy lifestyle. This change of a paradigm regarding causes of health and ill-health has to be seen in the context of changing disease patterns, modernity, and an adjustment in social identity. While during past centuries acute diseases constituted the major burden for health, during the last century chronic diseases gained importance and now account strongest for mortality. These chronic diseases can be influenced to a large degree by lifestyle in contrast to acute diseases. Modernity and changing social identities have as a consequence that theories gained importance, which postulate that individuals are agents of their lives who are free to choose their lifestyles (Beck, 1992).

Regarding the evolution of the term lifestyle in health sciences we can see that the meaning changed very much when compared to the way the term was initially conceptualized by Weber and Adler. Both argued that the lifestyle is related to a certain position within the social system, to a certain class and status. Most research in health sciences now postulates free choice of lifestyle regardless income, level of education, gender, or ethnicity. Structural influences on lifestyle are denied (see Cockerham, 2005). As a consequence, most recommendations for public health action are about public health interventions to reduce risk behavior like smoking and to enforce health behavior like exercise and healthy diet. These public health interventions often fail. They reach individuals with high SES

(high income and high education) who already pursue a healthy lifestyle, but they fail to reach low-SES individuals who maintain their unhealthy lifestyle.

More recent approaches referring to Weber and Bourdieu are important for health lifestyle research. These approaches include the interplay between life chances and life choices, the interplay between structure and agency in their research on reproduction of and on possibilities to change health lifestyles (Cockerham, 2005). Some research on health lifestyle includes the idea of the importance of social capital for health. It has been shown that social capital is an important determinant of health but the corresponding theoretical approaches differ strongly. Most studies refer to Robert Putnam (Putnam, 2000) and Ichiro Kawachi (Kawachi et al., 2008) who are representatives of agency theory. As an element of structure they refer to affiliations to concrete groups, whereas Bourdieu refers to the belonging to a class, to individuals who do not know each other, but have certain properties in common and access to the same resources. This difference between group and class is one of the main differences between the different definitions of social capital.

Even if it has to be stated that still most research on health lifestyles is strongly committed to agency theory, some research (see for example Cockerham, 2005) argues that living conditions, socialization, and experience as well as life chances in general should be studied in their interplay with life choices in order to analyze health lifestyles. The concept of the habitus as dispositions for life choices, actions, and practices of daily life seems to gain importance in health lifestyle studies.

Lifestyle in Leisure and Market Sciences

Research on lifestyle in leisure studies is mostly empirical and few studies refer to social theory as it is the case in health sciences and most other social science disciplines. Most lifestyle typologies in leisure and market research are constructed by means of quantitative methods like factor- and cluster analyses.

In marketing research, lifestyle is an important topic since the 1960s. The interest in marketing research is mostly oriented on variation in buying behavior with the aim to reach better results in marketing. In the 1960s, marketing research found that there was more variation in buying behavior within social classes than between them. Studies resulted in typologies like the VALS (Values, Attitudes and Lifestyles) typology of nine American lifestyle groups. Typologies like this one describe groups of distinctive consumption patterns and leisure behavior.

Other approaches in leisure and lifestyle research point out the importance of space and geographical location of the persons. Studies on suburban lifestyle have to be named in this context. Spatial approaches on lifestyle are concerned to build typologies including housing conditions, socioeconomic and sociodemographic factors, and their influence on leisure and consumption behaviors. The underlying assumption of spatial approaches is a spatial embeddedness of these behaviors and the idea that they differ between persons and groups living at different locations.

The different approaches to research on lifestyle in leisure and market studies have in common, that most of them do not focus on or not even take into account class and status position of the persons and that they do not include theoretical assumptions on social structure (see Veil, 2000).

Conclusion

Concluding it can be stated that the term lifestyle gained importance since it has been conceptualized by Weber and Adler, and it still gains of importance in many different disciplines of the social sciences like sport sciences, sustainability studies, the field of health studies, and sociology. But even if the term is used, its meaning differs between and within the disciplines. Therefore it can be argued, that the term spreads but with a broad meaning, which in some contexts seems to be very far away from its initial meaning.

Abstract

A statistical model for phenomena in the social sciences is a mathematical construct that associates a 'probability' with each of the possible outcomes. If the data are discrete, such as the numbers of people falling into various classes, the model will be a discrete probability distribution, but if the data consist of measurements or other numbers that may take any values in a continuum, the model will be a continuous probability distribution. When two different models, or perhaps two variants of the same model differing only in the value of some adjustable parameter(s), are to be compared as explanations for the same observed outcome, the probability of obtaining this particular outcome can be calculated for each and is then known as the 'likelihood' for the model or parameter value(s) given the data. The concept of likelihood, which was introduced by R.A. Fisher, plays an important role in all approaches to statistical inference, in particular allowing many of the advantages perceived for Bayesian methods without embracing their controversial prior probabilities.

A statistical model for phenomena in the sciences or social sciences is a mathematical construct, which associates a *probability* with each of the possible outcomes. If the data are discrete, such as the numbers of people falling into various classes, the model will be a discrete probability distribution, but if the data consist of measurements or other numbers that may take any values in a continuum, the model will be a continuous probability distribution. When two different models, or perhaps two variants of the same model differing only in the value of some adjustable parameter(s), are to be compared as explanations for the same observed outcome, the probability of obtaining this particular outcome can be calculated for each and is then known as the *likelihood* for the model or parameter value(s) given the data. This article enlarges on the definition of likelihood, discusses its properties and uses, and relates it to other approaches to statistical inference.

Probability and Likelihood Distinguished

Probabilities and likelihood are easily (and frequently) confused, and it is for this reason that in 1921 R.A. Fisher introduced the new word: "What we can find from a sample is the likelihood of any particular value of [the parameter], if we define the likelihood as a quantity proportional to the probability that, from a population having that particular value, the [observed sample] should be obtained. So defined, probability and likelihood are quantities of an entirely different nature" (*see* Fisher, Ronald A. (1890–1962)).

The first difference to be noted is that the variable quantity in a likelihood statement is the hypothesis (a word that conveniently covers both the case of a model and of particular parameter values in a single model), the outcome being that actually observed, in contrast to a probability statement, which refers to a variety of outcomes, the hypothesis being assumed and fixed. Thus a manufacturer of dice may reasonably assert that the outcomes 1, 2, 3, 4, 5, 6 of a throw each have 'probability' 1/6 on the hypothesis that his dice are well-balanced, while an inspector of casinos charged with testing a particular die will wish to compute the 'likelihood' for various hypotheses about these probabilities on the basis of data from actual tosses.

The second difference arises directly from the first. If all the outcomes of a statistical model are considered their total probability will be 1, since one of them must occur and they are mutually exclusive; but since in general hypotheses are not exhaustive – one can usually think of another one – it is not to be expected that the sum of likelihoods has any particular meaning, and indeed there is no addition law for likelihoods corresponding to the addition law for probabilities. It follows that only 'relative' likelihoods are informative, which is the reason for Fisher's use of the word 'proportional' in his original definition.

The Likelihood Function

The most important application of likelihood is in parametric statistical models. Consider the simplest binomial example, such as that of the distribution of the number of boys r in families of size n (an example which has played an important role in the development of statistical theory since the early eighteenth century). The probability of getting exactly r boys will be given by the binomial distribution indexed by a parameter p, the probability of a male birth. Denote this probability of r boys by $\mathrm{P}(r|p)$, n being assumed fixed and of no statistical interest. Then we write

$$\mathrm{L}(p||r) \propto \mathrm{P}(r|p)$$

for the likelihood of p given the particular value r, the double vertical line || being used to indicate that the likelihood of p is not conditional on r in the technical probability sense. In this binomial example, $\mathrm{L}(p||r)$ is a continuous function of the parameter p and is known as the 'likelihood function.' When only two hypotheses are compared, such as two particular values of p in the present example, the ratio of their likelihoods is known as the 'likelihood ratio.'

The value of p that maximizes $\mathrm{L}(p||r)$ for an observed r is known as the 'maximum-likelihood estimate' of p and is

denoted by p; expressed in general form as a function of r, it is known as the 'maximum-likelihood estimator.' Since the pioneering work of Fisher in the 1920s, it has been known that maximum-likelihood estimators possess certain desirable properties under repeated sampling (consistency and asymptotic efficiency, and in an important class of model sufficiency and full efficiency). For this reason, they have come to occupy a central position in repeated-sampling (or 'frequentist') theories of statistical inference (*see* Estimation: Point and Interval). However, partly as a reaction to the unsatisfactory features, which repeated-sampling theories display when used as theories of evidence, coupled with a reluctance to embrace the full-blown Bayesian theory of statistical inference, likelihood is increasingly seen as a fundamental concept enabling hypotheses and parameter values to be compared directly.

The Likelihood Principle

The basic notion, championed by Fisher as early as 1912 while still an undergraduate at Cambridge but now known to have been occasionally suggested by other writers even earlier, is that the likelihood ratio for two hypotheses or parameter values is to be interpreted as the degree to which the data support the one hypothesis against the other. Thus a likelihood ratio of 1 corresponds to indifference between the hypotheses on the basis of the evidence in the data, while the maximum-likelihood value of a parameter is regarded as the 'best-supported value,' other values being ranked by their lesser likelihood accordingly. This was formalized as the *Law of Likelihood* by Ian Hacking (1965). Fisher's final advocacy of the direct use of likelihood will be found in his last book *Statistical Methods and Scientific Inference* (1956).

Such an approach, unsupported by any appeal to repeated-sampling criteria, is ultimately dependent on the primitive notion that the best hypothesis or parameter value on the evidence of the data is the one which would explain what has in fact been observed with the highest probability. The strong intuitive appeal of this can be captured by recognizing that it is the value which would lead, on repeated sampling, to a precise repeat of the data with the least expected delay. In this sense it offers the best statistical explanation of the data.

In addition to specifying that relative likelihoods measure degrees of support, the likelihood approach requires us to accept that the likelihood function or ratio contains all the information we can extract from the data about the hypotheses in question on the assumption of the specified statistical model – the so-called 'Likelihood Principle.' It is important to include the qualification requiring the specification of the model, first because the adoption of a different model might prove necessary later, and second because in some cases the structure of the model enables inferences to be made in terms of 'fiducial probability' which, though dependent on the likelihood, are stronger, possessing repeated sampling properties, which enable confidence intervals to be constructed (*see* Fiducial and Structural Statistical Inference).

Though it would be odd to accept the 'Law of Likelihood' and not the 'Likelihood Principle,' Bayesians necessarily accept the Principle but not the Law, for although the likelihood is an intrinsic component of Bayes' Theorem, Bayesians deny that a likelihood function or ratio has any meaning in isolation. For those who accept both the Law and the Principle, it is convenient to express the two together as:

> *The Likelihood Axiom:* Within the framework of a statistical model, all the information which the data provide concerning the relative merits of two hypotheses is contained in the likelihood ratio of those hypotheses on the data, and the likelihood ratio is to be interpreted as the degree to which the data support the one hypothesis against the other.
>
> (Edwards, 1972)

The likelihood approach has many advantages apart from its intuitive appeal. It is straightforward to apply because, the likelihood function is usually simple to obtain analytically or easy to compute and display. It leads directly to the important theoretical concept of 'sufficiency' according to which the function of the data that is the argument of the likelihood function itself carries the information. This reduction of the data is often a simple 'statistic,' such as the sample mean (*see* Statistical Sufficiency). Moreover, the approach illuminates many of the controversies surrounding repeated-sampling theories of inference, especially those concerned with ancillarity and conditioning. Birnbaum (1962) argued that it was possible to derive the 'Likelihood Principle' from the concepts of sufficiency and conditionality, but to most people the Principle itself seems the more primitive concept and the fact that it leads to notions of sufficiency and conditioning seems an added reason for accepting it.

Likelihoods are multiplicative over independent data sets referring to the same hypotheses or parameters, facilitating the combination of information. For this reason 'log-likelihood' is often preferred because information is then combined by addition. In the field of genetics, where likelihood theory is widely applied, the log-likelihood with the logarithms taken to the base 10 is known as a LOD, but for general use natural logarithms to the base e are to be preferred, in which case log-likelihood is sometimes called 'support.' Most importantly, the likelihood approach is compatible with Bayesian statistical inference in the sense that the posterior Bayes distribution for a parameter is, by Bayes' Theorem, found by multiplying the prior distribution by the likelihood function. Thus when, in accordance with Bayesian principles, a parameter can itself be given a probability distribution (and this assumption is the Achilles' heel of Bayesian inference) all the information the data contain about the parameter is transmitted via the likelihood function in accordance with the 'Likelihood Principle.' It is indeed difficult to see why the medium through which such information is conveyed should depend on the purely external question of whether the parameter may be considered to have a probability distribution, and this is another powerful argument in favor of the Principle itself.

Parameter Estimation

In the case of a single parameter the likelihood function or the log-likelihood function may easily be drawn, and, if it is

unimodal, limits may be assigned to the parameter, analogous to the confidence limits of repeated-sampling theory. Calling the log-likelihood the 'support,' m-unit support limits are the two-parameter values astride the maximum at which the support is m units less than at the maximum. For the simplest case of estimating the mean of a normal distribution of known variance the 2-unit support limits correspond closely to the 95% confidence limits which are at ± 1.96 standard errors. In this normal case the support function is quadratic and may therefore be characterized completely by the maximum-likelihood estimate and the curvature at the maximum (the reciprocal of the radius of curvature) which is defined as the 'observed information.' Comparable definitions apply in multiparameter cases, leading to the concept of an m-unit support region and an observed information matrix. In cases in which the support function is not even approximately quadratic the above approach may still be applied if a suitable transformation of the parameter space can be found.

The representation of a support function for more than two parameters naturally encounters the usual difficulties associated with the visualization of high-dimensioned spaces, and a variety of methods have been suggested to circumvent the problem. It will often be the case that information is sought about some subset of the parameters, the others being considered to be nuisance parameters of no particular interest. In fortunate cases it may be possible to restructure the model so that the nuisance parameters are eliminated, and in all cases in which the support function is quadratic (or approximately so) the dimensions corresponding to the nuisance parameters can simply be ignored. Several other approaches are in use to eliminate nuisance parameters. Marginal likelihoods rely on finding some function of the data that does not depend on them; notable examples involve the normal distribution, where a marginal likelihood for the variance can be found from the distribution of the sample variance, which is independent of the mean, and a marginal likelihood for the mean can similarly be found using the t-distribution. Profile likelihoods, also called maximum relative likelihood, are found by replacing the nuisance parameters by their maximum-likelihood estimates at each value of the parameters of interest. It is easy to visualize from the case of two parameters why this is called a profile likelihood.

Naturally, a solution can always be found by strengthening the model through adopting particular values for the nuisance parameters, just as a Bayesian solution using integrated likelihoods can always be found by adopting a prior distribution for them and integrating them out, but such assumptions do not command wide assent. When a marginal likelihood solution has been found it may correspond to a Bayesian integrated likelihood for some choice of prior, and such priors are called neutral priors, to distinguish them from so-called uninformative priors for which no comparable justification exists. However, in the last analysis there is no logical reason why nuisance parameters should be other than a nuisance, and procedures for mitigating the nuisance must be regarded as expedients.

Relation to Significance Testing

All the common repeated-sampling tests of significance have their analogues in likelihood theory, and in the case of the normal model it may seem that only the terminology has changed. At first sight an exception seems to be the χ^2 goodness of fit test, where no alternative hypothesis is implied. However, this is deceptive, and a careful analysis shows that there is an implied alternative hypothesis that allows the variances of the underlying normal model to depart from their multinomial values. In this way the paradox of small values of χ^2 being interpreted as meaning that the model is 'too good' is exposed, for in reality they mean that the model is not good enough and that one with a more appropriate variance structure will have a higher likelihood. Likelihood ratio tests are based on the distribution under repeated-sampling of the likelihood ratio and are therefore not part of likelihood theory.

When likelihood arguments are applied to models with continuous sample spaces it may be necessary to take into account the approximation involved in representing data, which are necessarily discrete, by a continuous model. Neglect of this can lead to the existence of singularities in the likelihood function or other artifacts that a more careful analysis will obviate.

It is often argued that in comparing two models by means of a likelihood ratio, allowance should be made for any difference in the number of parameters by establishing a 'rate of exchange' between an additional parameter and the increase in log-likelihood expected. The attractive phrase 'Occam's bonus' has been suggested for such an allowance (Edwards, 1969). However, the proposal seems only to have a place in a repeated-sampling view of statistical inference, where a bonus such as that suggested by Akaike's information criterion is sometimes canvassed.

The major application of likelihood theory so far has been in human genetics, where log-likelihood functions are regularly drawn for recombination fractions (linkage values) (see Ott, 1991), but even there a reluctance to abandon significance testing altogether has led to a mixed approach. Other examples, especially from medical fields, will be found in the books cited below.

History and Further Reading

Although historically the development of a likelihood approach to statistical inference was almost entirely due to R.A. Fisher, it is interesting to recall that the Neyman–Pearson approach to hypothesis testing derives ultimately from a remark of 'Student's' (W. S. Gosset) in a letter to E. S. Pearson in 1926 that "if there is any alternative hypothesis which will explain the occurrence of the sample with a more reasonable probability … you will be very much more inclined to consider that the original hypothesis is not true," a direct likelihood statement (quoted in McMullen and Pearson, 1939). Indeed, it has been remarked that "Just as support [log-likelihood] is Bayesian inference without the priors, so it turns out to be Neyman–Pearson inference without the 'errors'" (Edwards, 1972).

The literature on likelihood is gradually growing as an increasing number of statisticians become concerned at the inappropriate use of significance levels, confidence intervals and other repeated-sampling criteria to represent evidence. The movement is most advanced in biostatistics as may be seen from books such as Clayton and Hills (1993) and Royall (1997), but general texts such as Lindsey (1995) and Sprott

(2000) exist as well. Among older books Cox and Hinkley (1974) contains much that is relevant to likelihood, while Edwards (1972, 1992) was the first book to advocate a purely likelihood approach, and is rich in relevant quotations from Fisher's writings. The history of likelihood is treated by Edwards (1974; reprinted in Edwards, 1992).

Likelihoods that Eliminate Nuisance Parameters

Brunero Liseo, MEMOTEF, Sapienza Università di Roma, Viale Castro Laurenziano, Roma, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Elimination of nuisance parameters is a central problem in statistical inference, and has been formally studied in virtually all approaches to inference. Given a statistical model, a researcher tries to make inferences about an unknown state of nature ψ (assumed to lie within some set Ψ of possible states of nature) upon observing the value $Y = y$ of some random vector $Y = \{Y_1, ..., Y_n\}$ whose probability distribution is completely determined by ψ. If Y has a density function $f(y|\psi)$, strong arguments, generally known as "The Likelihood Principle" suggest that inference about ψ ought to depend upon Y only through the *likelihood function* $L(\psi) = f(y|\psi)$, which is to be viewed as a function of ψ for the given y. Rarely is the entire parameter ψ of interest to the analyst. It is common to select a parameterization $\psi = (\theta, \lambda)$ of the statistical model in a way that simplifies the study of the "parameter of interest," here denoted θ, while collecting any remaining parameter specification into a "nuisance parameter" λ. In this article, we review some of the ways that have been used or proposed for eliminating the nuisance parameter λ from the analysis to achieve some sort of "likelihood" $L^*(\theta)$ for the parameter of interest.

Introduction

Consider a given statistical model, that is a triad $(\mathcal{Y}, \mathcal{F}, \Psi)$, where $\mathcal{Y}$ is the sampling space, Ψ is the parameter space, and we assume $\Psi \subset \mathbb{R}^d$, for some integer d, and

$$\mathcal{F} = \{f(y;\psi), \psi \in \Psi, y \in \mathcal{Y}\}$$

is a family of probability distributions defined on $\mathcal{Y}$. In general, one is interested in a low dimensional function θ of the parameter vector ψ, say $\theta = \theta(\psi) \in \mathbb{R}^k$, with $k < d$. Modern parametric statistical theories, at least the approaches based on likelihood and Bayesian theories, aim at constructing a likelihood function which depends on θ only. If such a likelihood exists it will represent the basis upon which one can construct inferential procedures for the parameter of interest θ. In this article, we will review the most popular approaches to obtain a likelihood function which is free of the nuisance parameters λ. It is well known that a likelihood function is defined, as a function of the parameters, up to a proportionality constant. In the following, we will deliberately ignore such constant, and the likelihood function expression will be always preceded by the symbol $\propto$.

Historically, the seminal papers addressing the problem are Kalbfleisch and Sprott (1970) and Basu (1977). In the former paper, two important examples of "partial" likelihoods were introduced, namely the *marginal* and *conditional* likelihoods.

Marginal Likelihood

If, in our model, there exists a statistics $T = t(y)$ whose distribution only depends on θ, we can use this distribution as a marginal sampling model. In practice, if it is possible to write the density of y as

$$f(y;\theta,\lambda) = f_1(t;\theta) f_2(y|t;\theta,\lambda)$$

we may ignore the fact that f_2 depends on θ and use f_1 as a marginal likelihood for θ.

Example 1

Let $(Y_1, \ldots, Y_n)$ be n Gaussian random variable with mean λ and variance θ. The complete likelihood function is

$$L(\theta,\lambda) \propto \frac{1}{\theta^{n/2}} \exp\left(-\frac{1}{2\theta}\sum_{i=1}^{n}(y_i-\lambda)^2\right)$$
$$\propto \frac{1}{\theta^{n/2}} \exp\left(-\frac{n}{2\theta}\left[S^2 + (\bar{y}-\lambda)^2\right]\right)$$

Set $Z = nS^2/\theta = \sum_{i=1}^{n}(y_i - \bar{y})^2/\theta$. It is known that Z has a Chi-squared distribution with $n-1$ degrees of freedom, that is

$$f_Z(z) = \frac{z^{\frac{n-1}{2}-1} e^{-\frac{z}{2}}}{2^{\frac{n-1}{2}}\Gamma(\frac{n-1}{2})}$$

Using a simple linear transformation argument, one can see that the distribution of $\theta Z = nS^2$ is

$$f_{nS^2}(nS^2;\theta) = \frac{1}{\theta}\left(\frac{nS^2}{\theta}\right)^{\frac{n-1}{2}-1} \exp\left(-\frac{nS^2}{2\theta}\right) \frac{1}{2^{\frac{n-1}{2}}\Gamma(\frac{n-1}{2})}$$

So, one can use this density as a marginal likelihood for θ: after eliminating the unnecessary constants, one obtains

$$L_M(\theta;\mathbf{y}) \propto \frac{1}{\theta^{(n-1)/2}} \exp\left(-\frac{n}{2\theta}S^2\right)$$

In general, it is easy to find a marginal likelihood for statistical models with a group structure (Pace and Salvan, 1997).

Conditional Likelihood

In a related way, it is possible to define a conditional likelihood based on the distribution of some statistics whose conditional distribution is free of λ. If the model has a sufficient statistics (T,S), the likelihood function can be written as

$$L(\theta,\lambda;\mathbf{y}) = f_1(t|s,\theta,\lambda)\ f_2(s;\theta,\lambda)$$

If it happens that the term f_1 does not depend on λ, the distribution of $T|S$ may be used as a conditional likelihood

for θ. The efficiency of this approach depends on the amount of information which is lost by ignoring the term f_2 in the above expression.

Example 2

A capture-recapture experiment. A software code has N faults, with N unknown. Two reviewers independently check the code. Each reviewer detects each fault – independently of each other – with probability p. Let N_1 and N_2 be the number of faults detected by the two reviewers, and let M be the number of faults detected by both of them. Here the parameter of interest is $\theta = N$ and the nuisance parameter is $\lambda = p$. It is easy to see that N_1 and N_2 are independent binomial random variables with parameters (N, p) and the conditional distribution of $(M|N_1 = n_1, N_2 = n_2, N, p)$ is hypergeometric, that is

$$\Pr(M = m|N_1 = n_1, N_2 = n_2) = \binom{n_1}{m}\binom{N-n_1}{n_2-m}\Big/\binom{N}{n_2} \qquad [1]$$

Since the last expression does not depend on p, it can be used as a conditional likelihood for N. Conditional likelihoods are easy to determine if the sampling model belongs to the exponential family (Pace and Salvan, 1997).

Profile Likelihood and Its Ramifications

Apart from the simple group structure or the exponential family, it is rare to be able to derive a conditional or a marginal likelihood. A more general and popular approach is to substitute the unknown nuisance parameter with its conditional (on θ) maximum likelihood estimate. Thus we obtain the so-called *profile* likelihood

$$\widehat{L}(\theta) = L\left(\theta, \widehat{\lambda}_\theta\right) \qquad [2]$$

with $\widehat{\lambda}_\theta = \arg\max_\lambda L(\theta, \lambda)$. The main advantages of using a profile likelihood are listed below:

- The maximum profile likelihood estimate $\widehat{\theta}$ will coincide with the one obtained from the joint likelihood $L(\theta, \lambda)$.
- $\widehat{L}(\theta)$ is easy to compute, and the inverse of its observed Fisher information is equal to the lower right corner of the inverse of the observed Fisher information computed with the true likelihood.
- It is invariant with respect to reparameterizations of the nuisance parameter λ.
- Test and confidence regions based on the profile likelihood can be approximately computed.

The main drawbacks are as follows:

- The profile score vector has not zero mean.
- Replacing an unknown parameter with a point estimate may dramatically overestimate the precision of the inferential procedures. This danger is particularly serious when the nuisance parameter has large dimension.

Example 1 (continued)

The conditional maximum likelihood estimate for λ is of course the sample mean $\widehat{\lambda}_\theta = \bar{y}$, which does not depend on θ. The profile likelihood is then

$$\widehat{L}(\theta) \propto \frac{1}{\theta^{n/2}} \exp\left(-\frac{n}{2\theta}S^2\right) = \theta^{-1/2} L_M(\theta)$$

Example 2 (continued)

In the capture-recapture example, the joint likelihood is

$$L(N,p) \propto \binom{N}{n_1}\binom{N}{n_2} p^{n_1+n_2}(1-p)^{2N-n_1-n_2} \frac{\binom{n_1}{m}\binom{N-n_1}{n_2-m}}{\binom{N}{n_2}}$$
$$\propto \frac{N!}{(N-r)!} p^k (1-p)^{2N-k}$$

where $r = n_1 + n_2 - m$ is the total number of detected faults and $k = n_1 + n_2$. Then $\widehat{p}_N = \frac{k}{2N}$, and the profile likelihood is

$$\widehat{L}(N) \propto \frac{N!}{(N-r)!}\frac{(2N-k)^{2N-k}}{(2N)^{2N}} = \frac{N!}{(N-r)!}\frac{1}{(2N)^k}\left(1-\frac{k}{2N}\right)^{2N-k} \qquad [3]$$

The profile approach of replacing λ by its conditional maximum likelihood estimator, $\widehat{\lambda}_\theta$, would appear to be dangerous in that it ignores the uncertainty in λ. Example 1 demonstrates a very mild version of this problem; the profile likelihood has one more 'degree of freedom' than it should, given the replacement of λ by $\bar{y}$. Indeed, many of the modifications to profile likelihood that have been advanced have, as one of their primary goals, adjustments to account for nuisance parameter uncertainty. It is important to emphasize that such modifications can be crucial, especially because 'raw' likelihood procedures will typically be anti-conservative, erring on the side of suggesting more accuracy than is actually warranted.

Modifications of the Profile Likelihood

Many proposals have been done to overcome the limitations of the profile likelihoods. Most of them results in a multiplicative correction factor to $\widehat{L}$ although their derivations can be very different in spirit. Here we briefly discuss the most important and general proposals. See, for example, Fraser and Reid (2003) for more details.

Conditional Approximated Likelihood

Suppose that the nuisance parameter λ can be re-expressed into a new parameter $\xi = g(\lambda, \theta)$ such that θ and ξ are orthogonal, that is the Fisher expected information in the (θ, ξ) parameterization is block-diagonal. This is always possible when θ is scalar. In this case one can use an approximation of the conditional distribution of the data, given the conditional maximum likelihood estimator of ξ, say $\widehat{\xi}_\theta$. So we can define the *conditional approximated likelihood* or *conditional profile likelihood* (CPL) as (Cox and Reid, 1987)

$$L_{\mathrm{CPL}}(\theta) \propto \widehat{L}(\theta)\left|j_{\xi\xi}\left(\theta, \widehat{\xi}_\theta\right)\right|^{-\frac{1}{2}} \qquad [4]$$

Formula [4] is then a modification of [2] with the correction factor given by the square root of the inverse of observed Fisher matrix for the nuisance parameter, evaluated at $\xi = \widehat{\xi}_\theta$. The correction factor is a penalty factor accounting for the uncertainty on the estimation of ξ. The necessity of finding an orthogonal parameterization explains that the conditional profile likelihood is not invariant with respect to reparameterizations of the nuisance parameter.

Example 1 (continued)
The nuisance parameter λ is already orthogonal to θ; an easy calculation shows that $j_{\xi\xi}(\theta, \widehat{\xi}_\theta) = n/\theta$ so

$$L_{\mathrm{CPL}}(\theta) \propto \theta^{\frac{1}{2}}\widehat{L}(\theta) = L_M(\theta)$$

Example 2 (continued)
Since N is an integer parameter, the Fisher information quantity is not readily available here, and we cannot compute a $L_{\mathrm{CPL}}(N)$ in this example. There are proposals to circumvent this limitation: Lindsay and Roeder (1987) propose to use the linear difference score for models with integer parameters.

Modified Profile Likelihood

A limitation of L_{CPL} is the need of finding an orthogonal parameterization. This might be impossible when θ is a vector. To overcome this difficulty, a different modification to the profile likelihood has been proposed: although it can be introduced in several different ways (see, for example, Barndorff-Nielsen (1983) and Pace and Salvan (1997)), it is easily interpreted as a 'multiplicative' correction of the conditional profile likelihood. Its expression is

$$L_{\mathrm{MPL}}(\theta) \propto \widehat{L}(\theta)M(\theta) \propto \widehat{L}(\theta)\left|j_{\lambda\lambda}\left(\theta, \widehat{\lambda}_\theta\right)\right|^{-\frac{1}{2}}\left|\frac{\partial\widehat{\lambda}_\theta}{\partial\widehat{\lambda}}\right|^{-1} \qquad [5]$$

The last term, the derivative of the conditional maximum likelihood estimator with respect to the unconditional one, accounts for nonorthogonality of the parameters. The correction factor $M(\theta)$ may be written in several different ways: see, Severini (2000) for details.

Example 1 (continued)
Here the parameters are orthogonal, so $\widehat{\lambda}_\theta = \widehat{\lambda}$ and the $L_{\mathrm{MPL}}(\theta)$ coincides with $L_{\mathrm{CPL}}(\theta)$.

Integrated Likelihood

Let $q(\lambda;\ \theta)$ be a nonnegative weight function defined on Λ, possibly depending on θ, such that $\int_\Lambda |q(\lambda;\theta)|\mathrm{d}\lambda < +\infty$. An integrated likelihood function for the parameter of interest θ is then

$$\tilde{L}_q(\theta) \propto \int_\Lambda f(y;\theta,\lambda)q(\lambda;\theta)\mathrm{d}\lambda = f_q(y;\theta)$$

It is intuitive to see that a Bayesian would select $q(\lambda;\ \theta)$ as his/her conditional prior distribution for λ given θ, say $\pi(\lambda|\theta)$. As long as $\pi(\lambda|\theta)$ is a proper distribution this would correspond to the use of the marginal model $f_q(y;\ \theta)$: in this sense $L_q(\theta)$ is a genuine likelihood function. If π is improper, as it is often the case in the default noninformative approaches, this is not guaranteed and care must be taken in the choice of π. In practice, possible choices for $\pi(\lambda|\theta)$ are as follows:

- A subjectively chosen prior: this is advisable in the presence of genuine prior information about λ. When $\pi(\lambda|\theta)$ is naturally a proper conditional density, certain of the concerns with interpreting and using the resulting integrated likelihood disappear. In particular, the resulting integrated likelihood can unambiguously be interpreted as a likelihood and can be combined with any proper prior density for θ to produce a true posterior. Today it is popular for computational reasons to use 'vague' proper priors (often 'vague' conjugate priors). Unfortunately, the use of such does not really provide protection against the concerns that arise with use of improper conditional priors; if a difficulty would arise in using an improper conditional prior, the same difficulty would manifest itself through great sensitivity to the degree of 'vagueness' chosen.
- The uniform choice of $\pi(\lambda|\theta) = 1$ has already been mentioned. It is still the most commonly used default conditional prior and is an attractive choice when nothing else is available. There are, however, well-documented difficulties with the uniform prior, perhaps the most well known being its lack of invariance to reparameterization. Using the uniform prior for a positive parameter λ will yield a different integrated likelihood than using the uniform prior for its logarithm $\lambda^* = \log\lambda$, for example.
- A more sophisticated objective conditional prior, namely the *conditional reference prior*. The derivation of this conditional prior is a slight modification of the more popular reference prior approach proposed by Berger and Bernardo (1992) and it is discussed in detail in Berger et al. (1999).

Example 1 (continued)

In this case the nuisance parameter λ is the location parameter. Virtually every noninformative Bayesian approach would suggest to use an improper flat prior, that is $\pi(\lambda|\theta) \propto 1$. The resulting integrated likelihood is

$$\begin{aligned}\tilde{L}(\theta) &= \int_{-\infty}^{\infty} \frac{1}{\theta^{n/2}}\exp\left(-\frac{n}{2\theta}\left[S^2 + (\bar{y}-\lambda)^2\right]\right)\mathrm{d}\lambda \\ &= \frac{1}{\theta^{n/2}}\exp\left(-\frac{n}{2\theta}S^2\right)\int_{-\infty}^{\infty}\exp\left(-\frac{n}{2\theta}(\bar{y}-\lambda)^2\right)\mathrm{d}\lambda\end{aligned}$$

The last integrand is proportional to a Gaussian density so the value of the integral is $\sqrt{2\pi\theta/n}$. Then

$$\tilde{L}(\theta) \propto \frac{1}{\theta^{(n-1)/2}}\exp\left(-\frac{n}{2\theta}S^2\right) = L_M(\theta)$$

One could also use his/her own prior information and produce a subjective integrated likelihood. For example, one can assume that, a priori

$$\lambda|\theta \sim N(0, \theta/k)$$

This assumption is equivalent to say that the information provided by the prior corresponds to an extra observation whose precision is k times greater than the precision of the actual observations; of course k must be subjective elicited. In this case, one has

$$\tilde{L}(\theta) \propto \frac{1}{\theta^{n/2}} \exp\left(-\frac{n}{2\theta}S^2\right) \frac{1}{\sqrt{\theta}} \int_{-\infty}^{\infty} \exp\left(-\frac{n}{2\theta}(\lambda - \bar{y})^2\right) \times \exp\left(-\frac{k}{2\theta}\lambda^2\right) \mathrm{d}\lambda$$
$$\propto \frac{1}{\theta^{n/2}} \exp\left(-\frac{n}{2\theta}S^2\right) \exp\left(-\frac{nk}{2(n+k)\theta}\bar{y}^2\right)$$

Notice that, as $k \to 0$, $\tilde{L}(\theta)$ will converge point-wise to the profile likelihood $\widehat{L}(\theta)$, because of the 'extra' observation, which adds a degree of freedom.

Example 2 (continued)

Here a reasonable choice for the conditional prior for the nuisance parameter p is a symmetric Beta(a, a) density, that is

$$\pi(p|N) \propto p^{a-1}(1-p)^{a-1}$$

Simple algebra shows that in this case the integrated likelihood is

$$\tilde{L}_a(N) \propto \frac{N!}{(N-r)!} \frac{\Gamma(2N-k+a)}{\Gamma(2N+2a)} \qquad [6]$$

Notice that, in this example, the conditional uniform prior and the conditional reference prior are special cases of the above Beta prior. The former corresponds to $a = 1$ and the latter to $a = 0.5$. Using a Stirling approximation, that is $\Gamma(t+1) \approx 2\pi e^{-t} t^{t+1/2}$, we can see that for large N

$$\tilde{L}_a(N) \approx \frac{N!}{(N-r)!} \frac{1}{(2N+2a-1)^{k+a}} \left(1 - \frac{k+a}{2N+2a-1}\right)^{2N-k+a-\frac{1}{2}}$$

which, for $a = 1/2$, becomes

$$\tilde{L}_a(N) \approx \frac{N!}{(N-r)!} \frac{1}{(2N)^{k+\frac{1}{2}}} \left(1 - \frac{k+\frac{1}{2}}{2N}\right)^{2N-k}$$

qualitatively similar to the profile likelihood eqn [3].

Generally speaking, the most popular objective prior in Bayesian analysis, namely the Jeffreys' prior is not well suited for producing integrated likelihoods. The Jeffreys' prior approach, in fact, will produce a prior $\pi^J(\theta, \lambda)$ which is proportional to the square root of the determinant of the expected Fisher information matrix and this prior is not able to distinguish between the parameter of interest and the nuisance parameters; then it is technically difficult to separate $\pi^J(\lambda|\theta)$ from $\pi^J(\theta)$, since the Jeffreys' prior is usually improper, that is, its integral over the parameter space is not a finite number. The resolution of this difficulty is at the core of the development of the conditional reference prior approach in Berger et al. (1999).

Some Particular Models

In the previous section, we have described the most popular approaches to the elimination of nuisance parameters and we have illustrated them through very simple examples. Modern statistics, however, deals with more complicated models and new problems arise in this context. Consider our Example 2: we have assumed that there were only two reviewers and the probability of detecting a fault was the same for both of them. We can imagine that there might be more than two reviewers with different abilities. With k reviewers, our model would have a k-dimensional nuisance parameter $\tilde{p} = (p_1, \ldots, p_k)$ and it would be interesting to note how the previous methods would change in this setup. In the profile likelihood approach one has to estimate k different parameters now, and the amount of "hidden" uncertainty under the procedure may become very serious. With the integrated likelihood approach one needs to elicit k different conditional priors, or a k-dimensional prior, over $\tilde{p}$. This maybe a problem for large k although from a different perspective, it may represent an advantage, in those cases where one knows that the reviewers have different skills indeed! It is interesting to note that the conditional likelihood, in this particular situation, will only show minor changes; for $k = 2$ and $p_1 \neq p_2$, it would be exactly equal to eqn [1].

We conclude this review with a discussion on methods of eliminating nuisance parameters in more complex models. A nonexhaustive list of problems where the elimination of nuisance parameters is still a vivid research problem must include:

- Statistical models with many nuisance parameters
- Semiparametric problems.

Models with many nuisance parameters refer to a general class of models where subsets of observations share common parameters. This setup is known under different names in different fields of application: latent structure in social and medical statistics, stratum parameters (Sartori, 2003) in biostatistics, incidental parameters in econometrics. Consider again Example 2 and assume now that the probability of detecting an error depends on the error itself; in that case we would have a model with N (unknown) incidental parameters and some structure among them should be assumed in order to make valid inferences. In general, problems where the number of nuisance parameters increases with the sample size are challenging because the usual asymptotic theory does not hold. We will only consider here the historical and famous problem of many Normal means (Neyman and Scott, 1948). Consider n different sets of k i.i.d. Normal random variables with common variance θ and different means λ_j, that is

$$Y_{j1}, Y_{j2}, \ldots, Y_{jk} \overset{iid}{\sim} N\left(\lambda_j, \theta\right), \quad j = 1, \ldots, n$$

Let $\boldsymbol{\lambda} = (\lambda_1, \ldots, \lambda_n)$. The likelihood function is then

$$L(\theta, \boldsymbol{\lambda}) \propto \frac{1}{\theta^{nk/2}} \exp\left(-\frac{k-1}{2\theta} \sum_{j=1}^{n} S_j^2 + k(\bar{y} - \lambda_j)^2\right)$$

where S_j^2 is the usual unbiased estimate for the variance within a single sample. Since $\widehat{\lambda}_\theta = (\bar{y}_1, \bar{y}_2, \ldots, \bar{y}_n)$, the profile likelihood is

$$\widehat{L}(\theta) \propto \frac{1}{\theta^{nk/2}} \exp\left(-\frac{k-1}{2\theta} \sum_{j=1}^{n} S_j^2\right)$$

which is maximized at $\widehat{\theta} = (k-1)\sum S_j^2/(nk)$. Since the S_j^2's are i.i.d. r.v.'s with mean θ, the law of large numbers suggest

that $\widehat{\theta}$ is not even a consistent estimator since, as $n \to \infty$, $\widehat{\theta} \to (k-1)\theta/k$. The bad behavior of the $\widehat{L}(\theta)$ can be corrected either by using a modified profile argument or by integrating out $\boldsymbol{\lambda}$ with respect to a flat prior, which is incidentally the conditional reference prior for this problem, $\pi(\lambda) \propto 1$. Both of them introduce a correction factor of $\theta^{n/2}$ which leads to a consistent estimator of θ.

Loosely speaking, a semiparametric model is a model where the parameter space Ψ can be written as $\Theta \times \Lambda$, with $\Theta \subset \mathbb{R}^d$ for some integer d, while Λ is infinite dimensional. If θ is the parameter of interest, then inference on this model is a problem of elimination of the infinite dimensional nuisance parameters λ. This kind of models is getting very popular in applied statistics since today the increased availability of data makes it difficult to select a particular statistical model and, on the other hand, there is still a given quantity θ we are interested in.

Murphy and van der Vaart (2000) establish a first-order asymptotic likelihood theory for general classes of semiparametric models. Their approach is based on the construction of a least-favorable parametric family and then the usual asymptotic results are considered with respect to this family. In their framework the profile likelihood inherits many of its asymptotic properties for the parametric case. A detailed discussion of these issues is beyond the scope of this article. We limit ourselves to the discussion of a relatively simple, although meaningful, example of the construction of a semiparametric likelihood for the median of an unknown distribution (Liseo, 2005).

Example 3

Given $\theta \in \mathbb{R}$ and for a given continuous probability density $\lambda(\cdot)$, defined on $\mathbb{R}$ and having zero median, suppose we observe n i.i.d. random variables $Y_i = \theta + \varepsilon_i$, $i = 1, \ldots, n$, with $\varepsilon_i \sim \lambda(\cdot)$. We are interested in θ and λ is the infinite dimensional nuisance parameter. Consider the set $\mathcal{F}$ of all continuous, zero-median, probability density functions. This problem is very simple to state and it has been discussed in several papers: see Liseo (2005) for references. The infinite dimensionality of the nuisance parameter is a challenge for the techniques we have illustrated above. Non-Bayesian inference is usually performed via the construction of some ad-hoc pseudo-likelihood for θ. The original idea dates back to Jeffreys (1961), p. 211; let $K(\theta)$ be the number of observations in the sample which are not greater than θ. Then, for fixed θ, $K(\theta) \sim \mathrm{Bin}(n, 0.5)$ and a possible pseudo-likelihood for θ is

$$L_{\mathrm{PS}}(\theta) \propto \binom{n}{k(\theta)}$$

Notice that this likelihood is based on the distribution of K, which is not a statistic in the strict sense, since it depends on θ, so L_{PS} is not a genuine likelihood.

Alternatively one can maximize $L(\theta, \lambda)$ over the set $\mathcal{F}$, for fixed θ, thus obtaining the profile likelihood

$$\widehat{L}\left(\theta\right) \propto k(\theta)^{-k(\theta)}[n - k(\theta)]^{-[n-k(\theta)]}$$

Both the above likelihood functions have the drawback that they do not vanish for large values of $|\theta|$ and that makes hard their use in testing and confidence regions. A Bayesian analysis of the problem can be done by assuming a Polya tree prior for $\lambda(\cdot)$. Ghosal et al. (1999) show that, under some constraints on the choice of the parameters of the Polya tree, the posterior of θ will be consistent for a large class of true symmetric densities. However, this approach is not objective, since the final answer will depend on the hyperparameters of the Polya tree prior.

An alternative and general approach for computing an approximated integrated likelihood function is based on a novel use of ABC, namely Approximate Bayesian Computation. This approach is illustrated in Grazian and Liseo (in press) with several examples.

This article is a revision of the previous edition article by R.L. Isaacson, volume 13, pp. 8858–8862, © 2001, Elsevier Ltd.

Abstract

While the definition of the limbic system has evolved since Paul Broca first described the distinct set of cortical structures on the medial surface of the cerebrum, the major structures have remained fairly consistent. Here we describe the major anatomical structures most commonly included in the limbic system and explore their major behavioral and cognitive functions. In addition, we propose and alternative way of conceptualizing the limbic system as more than just the primary system for emotional processing.

Introduction

In order to characterize the functionality of the highly complex organ serving as the commander in chief of our nervous system, scientists often divide the brain into separate systems – clearly defined anatomically distinct regions and pathways that function together to interpret inputs. Commonly recognized sensory systems include those of vision, hearing, somatic sensation, taste, and olfaction. Beginning around 1930, scientists began to argue that there also exists a system for processing the experience of emotion. This argument was supported largely by the integration of Paul Broca's work in the 1870s and James Papez' in the 1930s. Broca (1878) noted that all mammals possess a group of cortical areas on the medial surface of the cerebrum that are distinctly different from the surrounding cortex. He named this collection of cortical areas the limbic lobe, after the Latin word limbus, which means 'border' or 'fringe.' Later, Papez (1937) proposed the idea of an 'emotional system' that involves several interconnected structures on the medial surface of the brain, many of which overlap with Broca's limbic lobe. Paul MacLean (1952) popularized the term 'limbic system' to describe the group of limbic and cortical structures that govern the experience and expression of emotion.

Experimental work supports the involvement of the limbic system in emotion processing; however, the limbic structures also play a role in a number of other functions, including learning and memory. As scientists have continued to develop new anatomical, physiological, and behavioral approaches to investigate the brain in both clinical and research settings, many cortical regions, nuclear groups, and tracts that are structurally and/or functionally interconnected with limbic regions have come to be considered part of this network, broadening the concept of the limbic system even further. For this reason, there is much disagreement in the scientific community about which structures should be included in the limbic system, and consequentially, what its overarching role might be in mental functions and behavior. In this article, we will (1) describe the anatomical brain regions *most commonly* associated with the limbic system, (2) explore important behavioral and cognitive functions of these structures, and (3) propose an alternative way of conceptualizing the limbic system.

Anatomy of the Limbic System

It is important to have an anatomical understanding of the major structures and tracts of the limbic system before we delve into its functions. In this section, we will provide a basic anatomical overview, however, the connections and interactions between these areas and other brain regions are much more extensive than the scope of this article. We will discuss the major nuclear groups, limbic cortex, and fiber tracts that form the structural foundation of the limbic system. A schematic representation of these structures and connections is shown in Figure 1.

Nuclear Groups and Major Structures

Amygdala

Perhaps the most featured structure in recent research on the limbic system is the amygdala. This almond-shaped formation on the medial temporal lobe sits immediately anterior to the hippocampi and is often divided into three nuclei: the basolateral nucleus, the corticomedial nucleus, and the central nucleus. Due to its distinct functions, the basolateral nucleus can be further subdivided into the basal and lateral amygdala. One unique feature of the amygdala is that it receives afferents from neocortex in each lobe of the brain and each sensory system, as well as the hippocampal and cingulate gyri (Young et al., 1994). Additionally, the interconnections between the amygdala nuclei allow for the integration of information from each sensory system. Its extensive connectivity makes the amygdala ideally suited for valence-laden modulation of memory and emotional processing.

Hippocampal Formation and Associated Structures

The hippocampal formation is a folded structure in the medial temporal lobe consisting of the hippocampus and subiculum. Additionally, there are three cortical regions ventral to the hippocampus that are highly interconnected with the hippocampal formation: the entorhinal cortex, the perirhinal cortex, and the parahippocampal gyrus. Like the amygdala, these regions receive inputs from all sensory modalities, allowing for the integration of complex sensory information. The entorhinal cortex is the main source of input to the hippocampal formation, sending information to the hippocampus through

Figure 1 Major structures and connections of the limbic system.

a bundle of axons called the perforant path. From the hippocampus, information is carried in a C-shaped bundle of fibers called the fornix to the hypothalamus and mamillary bodies. Research implicates the hippocampus in consolidation of declarative and spatial memories (Squire, 1992).

Hypothalamus and Mamillary Bodies

The hypothalamus is a diencephalic structure surrounding the third ventricle below the thalamus. Due to its extensive reciprocal connections with almost every major part of the central nervous system including the cerebral cortex, hippocampus, amygdala, brain stem, and spinal cord, it is responsible for a wide variety of regulatory functions. In the context of the limbic system, multisynaptic cerebral pathways relay processed information to the hypothalamus, which regulates various kinds of emotional responses accompanied by physiological arousal through the autonomic nervous system (ANS) (Powley and Laughton, 1981). The mamillary bodies are located at the caudal end of the hypothalamus, but they have different functional responsibilities than the other hypothalamic nuclei. Namely, they are not as responsible for autonomic and endocrine functions, but instead serve more as relay nuclei for information coming from the medial temporal lobes and traveling to the anterior thalamus and eventually the cingulate cortex (Irle and Markowitsch, 1982).

Septal Nuclei and Nucleus Accumbens

The septal nuclei are a set of structures inferior to the rostrum of the corpus callosum and anterior to the lamina terminalis. These nuclei have a wide array of reciprocal projections with many brain structures, such as the hippocampus, amygdala, hypothalamus, midbrain, habenula, cingulate gyrus, thalamus, and olfactory bulbs (Raisman, 1966). Along with the nucleus accumbens, which is a part of the ventral striatum, the septal nuclei play a role in reward and reinforcement (Zahm, 2000).

Limbic Cortex

The human neocortex is typically organized into six distinct layers. In Paul Broca's original observations, he noted that all mammals possess a group of cortical areas on the medial surface of the brain that do not follow the normal neocortical organization, but instead show a simpler cellular organization with only three cortical layers. It is this deep band of phylogenetically older tissue that Broca originally named 'the great limbic lobe.' This cortex is now referred to as paralimbic cortex due to its proximity to other limbic structures and includes the cingulate gyrus, subgenual cortex, dentate gyrus, and parahippocampal gyrus. The anterior portion of the parahippocampal gyrus is occupied mostly by entorhinal cortex, a region closely related to the hippocampus. The remainder of the anterior parahippocampal gyrus is part of piriform cortex, which also includes the cortical amygdala and uncus.

As research on memory and emotion has progressed, some neocortical regions have been included in the limbic system. One of these regions is the orbitofrontal cortex, mainly due to its role in emotion and reward (Kringelbach, 2005). This region of the prefrontal cortex has direct and indirect (via the thalamus) connections with the hippocampus and associated neocortex, the amygdala, and the hypothalamus.

Fiber Tracts

Medial Forebrain Bundle

The medial forebrain bundle is perhaps the most well-known hypothalamic fiber tract. Unlike some neural pathways, this tract does not form a well-defined 'bundle' as the name suggests, but instead the term is used to designate a heterogeneous group of axons that run through the lateral hypothalamus. Through descending fibers, this bundle can directly influence preganglionic sympathetic and parasympathetic nuclei in the brain stem and spinal cord. Additionally, some of these fibers connect the amygdaloid body with the lateral hypothalamus and other forebrain regions, allowing the forebrain and limbic regions to modulate both somatic and visceral activity (Powley and Laughton, 1981). This is one example of how information about the body's physical state of arousal is integrated and modulated through limbic structures and connections.

Fornix

The fornix is a large fiber bundle that travels anteriorly through the thalamus, eventually terminating in the medial and lateral parts of the hypothalamus, mamillary bodies, septal nuclei, and nucleus accumbens. Both the hippocampus and amygdala have extensive projections to the hypothalamus through the fornix. Many neurons from the subiculum of the hippocampal formation travel through the fornix and eventually terminate in the mamillary bodies. Efferents from the mamillary bodies travel through the mamillothalamic tract to the anterior thalamus.

Stria Terminalis and Ventral Amygdalofugal Bundle

The stria terminalis is a projection of reciprocal fibers that connect the amygdaloid body and the medial hypothalamus. It follows a similar trajectory as the fornix, traveling dorsally behind and above the thalamus. In the region of the anterior commissure, the stria terminalis divides and distributes fibers to the bed nucleus of the stria terminalis, the medial hypothalamus, and other areas of the basal forebrain. This tract allows the amygdala to regulate hypothalamic functions. Like the stria terminalis, the ventral amygdalofugal bundle also arises from neurons in the amygdala and terminates in the hypothalamus. These tracts between the amygdala and the hypothalamus essentially allow the amygdala to indirectly regulate the endocrine and autonomic components in the expression of emotional responses.

Functions of the Limbic System

The more we explore the neural circuitry driving emotion, cognition, and behavior, the more we discover the extensive role of limbic system structures in these processes. Here, we will explore some of the specific roles of 'limbic system' networks, which include the structures described above, in emotion, learning and memory, attention and social processing.

Emotional Memory

Klüver and Bucy (1937) were among the first to demonstrate the role of temporal lobe structures, particularly the amygdala, in emotion when they demonstrated that medial temporal lobe lesions in rhesus monkeys resulted in a range of odd behaviors, including approaching feared objects and exhibiting an array of unusual sexual behaviors. The most dramatic emotional change in the monkeys with bilateral temporal lobectomies was a marked decrease in fear and aggression, implicating temporal lobe structures in regulating emotional responses. Since then, huge strides have been made in uncovering the role of the amygdala and other associated brain regions in mediating emotional influences on attention, perception, and regulation of emotional responses (Phelps, 2006).

When discussing emotion in the context of the limbic system, there are two phenomena in emotional memory that should be addressed. First, there is the process of associating positive or negative emotional dispositions toward previously neutral stimuli. Much of the focus of research on this emotional association learning has been on the neural mechanisms of fear (Davis, 1992; LeDoux, 2000; Fanselow and Gale, 2003), so we will limit our exploration of the neural mechanisms of emotion to this circuit. Second, there is the widely observed phenomenon whereby memories for events that resulted in emotional arousal tend to be more accurate and longer lasting than memories of neutral events (Berlyne, 1969; Heuer and Reisberg, 1992; Kleinsmith and Kaplan, 1963). This mechanism for memory storage is evolutionarily adaptive, as emotional memories are generally the ones that an organism needs to remember the most. Interestingly, the amygdala is implicated in both of these situations.

In order to survive and thrive in an environment, it is imperative that an organism be able to form affective associations between sensory information and situation. This is particularly true for learned fear. Through socialization or painful experience, an organism must learn to avoid certain behaviors to escape/avoid harm. These fear associations are mediated by the amygdala independently of the events in which the disposition was acquired (Kim and Fanselow, 1992; Phillips and LeDoux, 1992). In other words, normal emotional conditioning can occur even if declarative memory for the learning situation is impaired (e.g., through hippocampal damage). In a fearful situation, sensory information reaches the basolateral nucleus of the amygdala, and the signal is then relayed to the central nucleus. Efferents from the central nucleus project to the hypothalamus and other subcortical areas controlling a broad range of fear-related responses, including activation of the sympathetic nervous system and motor behavior (e.g., increases in heart rate, blood pressure, perspiration, startle response somatomotor immobility, and ultrasonic vocalizations) (for reviews, see Sarter and Markowitsch, 1985; Kapp et al., 1992; McGaugh et al., 1992). After these associations have been established, if the organism later finds itself in a situation resembling the one in which the fear association was created, then it will demonstrate these fear-related responses, even in the absence of the fearful stimulus itself.

To address the assertion that memories tied to emotional events are stronger and more vivid than neutral memories, again the amygdala comes into play. The role(s) of the amygdala in modulating the consolidation of memories of emotionally arousing experiences has been extensively studied over the past several decades. These processes are beyond the

scope of this article, but are detailed in other recent reviews (McGaugh, 2004; Phelps, 2006; Schultz, 2006; Shors, 2006). In summary, when an event happens that is emotionally arousing, epinephrine and glucocorticoids are released by the adrenal glands in response to increased activity in the ANS. This leads to an increase in norepinephrine and consequentially an increase in activity in the amygdala. Evidence from a large number of animal studies suggests that the amygdala's connections with the striatum, hippocampus, neocortex, and nucleus basalis (an indirect path that leads to innervation of much of the cortex) allow it to mediate memory consolidation in other brain regions in response to an emotional event. In other words, the consolidation of what would simply be a declarative memory is enhanced in situations that evoke strong emotions. While the involvement of the amygdala in creating stimuli associations is somewhat independent, this particular phenomenon works in conjunction with the next network that will be discussed: the hippocampal memory system.

The Hippocampal Memory System

Current evidence suggests that there are multiple memory systems that are governed by distinct and interacting neural substrates. These memory systems compete, collaborate, and/or, work in parallel to support and drive behavior. We discussed the amygdala's role in emotional memory in the previous section. Here, we will focus the other major memory system that is closely linked to the limbic system: the hippocampal memory system.

The hippocampal memory system involves the hippocampal formation and regions of the cerebral cortex that serve both as a source of information to the hippocampus and parahippocampal gyrus and as targets for hippocampal projections. Research on the involvement of the hippocampus in memory was sparked by an epilepsy patient in the 1950s named Henry Molaison, known famously as H.M. In order to control his seizures, a neurosurgeon named William Scoville removed a substantial amount of tissue from the medial aspect of Molaison's temporal lobes. While the surgery alleviated his seizures, Molaison was left with severe anterograde amnesia and showed almost no capacity for new episodic learning (Scoville and Milner, 1957). Molaison's memory deficits were first characterized by Brenda Milner, who performed a battery neuropsychological test on him. Ultimately, she revealed that while Molaison showed profound memory deficits, his intellectual and perceptual abilities were generally normal, he was able to hold small amounts of information as long as he was actively rehearsing the information, his childhood memories were intact and he had the ability to acquire new motor skill learning (Milner, 1962). This was some of the first evidence that neural mechanisms underlying procedural and declarative, as well as short-term and long-term memory, are not identical.

Our understanding of memory systems has advanced greatly since the H.M. case. There is now a large body of literature that describes how damage to the hippocampus and parahippocampal regions results in the inability of the brain to consolidate new declarative memories, while perceptual, motor, and intellectual functions remain largely intact. For a long time, based on the observation from human lesion studies, it was thought that the key structures that lead to a deficit in declarative memory consolidation were the hippocampus and amygdala. However, research now shows that selective lesions to the amygdala and hippocampus can have little or no effect on recognition memory and may only produce mild amnesia (Mishkin, 1978). The most severe memory deficits actually result from damage to the perirhinal cortex, which is an area of cortex where information from all sensory modalities converges before it is relayed to the hippocampus (Zola-Morgan et al., 1989). Hippocampal damage may also result in retrograde memory loss, but this effect is time-limited (Kim and Fanselow, 1992). In other words, the hippocampal formation is involved in memory consolidation and reconsolidation for a certain period of time, but once the memory has been represented in the brain for a prolonged period of time, memory retrieval can be supported by other areas of the brain. Scientists have hypothesized distinct roles for the hippocampus and associated cortices in learning and memory, but thus far, there is no general consensus about the distinction.

One popular line of research that aims to form a causal link between the hippocampus and memory formation stems from the discovery of long-term potentiation (LTP) by Terje Lømo in 1966 in Oslo, Norway, laboratory of Per Andersen (Lømo, 1966). There, Lømo and his collaborator Timothy Bliss conducted a series of neurophysiological experiments in both anesthetized and unanesthetized rabbits in which they were able to observe rapid and persistent increases in synaptic strength in postsynaptic neurons of the dentate gyrus induced by a brief burst of stimulation in presynaptic neurons in the perforant path (Bliss and Lømo, 1973; Bliss and Gardner-Medwin, 1973). Subsequent studies have shown that there are many mechanisms for the induction of LTP in many additional areas of the brain (e.g., cerebellum, neocortical regions, and the amygdala). The tremendous experimental interest in LTP is driven by the working hypothesis that this form of synaptic plasticity may participate in encoding and retrieval of information. Hebbian forms of LTP exhibit associativity, which supports the postulate that LTP is a neural correlate of learning and memory. However, while evidence is accumulating for the causal link between LTP and memory (e.g., Martin et al., 2000; Whitlock et al., 2006), the task has proven to be rather difficult.

The hippocampal formation is also involved in spatial memory and navigation. This idea stemmed from rodent research in the 1970s by John O'Keefe and his colleagues that described neurons in the hippocampus that showed activity in response to the rat's location in its environment (O'Keefe and Dostrovsky, 1971). Since then, place responses in rodents have been investigated in hundreds of experiments, and while there is still no general consensus on the exact mechanisms of spatial navigation or whether these place cells exist in the human brain, there is now almost universal agreement that spatial coding plays a large role in hippocampal function.

Lesions in areas of the brain outside the temporal lobes that receive projections from the hippocampus through the fornix can also lead to memory deficits. Recall from the anatomy section that neurons from the hippocampal formation project to the hypothalamus and mamillary bodies through the fornix, from the mamillary bodies to the anterior nucleus of the thalamus through the mamillothalamic tract, and then from

the thalamus to the cingulate cortex. Evidence suggests that lesions to any of these structures may leads to mild or severe memory deficits, depending on the size and location of the lesions (Aggleton et al., 1995; Ennaceur et al., 1997; Kapur et al., 1996).

Additional Roles of Limbic System Structures

As we have discussed above, in order to address questions of how complex psychological functions are produced by specific neural circuits, a series of neural 'systems' have been constructed to describe specific functions. However, at a certain level of behavioral complexity, it becomes difficult to create clear definitions between these systems. We have already discussed the extensive role of limbic system structures in emotion, learning, and memory. As behaviors and cognitions become increasingly complex, emotion and memory become critical components of more complex processes such as reward, motivation, and social processing. For example, in the absence of immediate goals, an organism must be able to use the memory of past experiences and associations to predict the likelihood of an occurrence. This classical or instrumental learning reinforces certain behaviors, and – in conjunction with the nigrostriatal and mesolimbic dopamine systems – is crucial in mediating the processes of reward and motivation (Wise, 2004).

The limbic system, specifically the amygdala, is also involved in social processing. In fact, one of the first studies of human amygdala lesions showed that bilateral amygdala damage can lead to impairments in the processing of faces and other social signals (Jacobson, 1986). Later lesion and functional neuroimaging studies confirm the importance of the amygdala in processing emotional facial expressions, especially fear (Adolphs et al., 1994; Anderson et al., 2003; Breiter et al., 1996; Morris et al., 1996). Additional evidence suggests that the amygdala's response to facial expressions can be conditioned (Morris et al., 1998), implicating that the amygdala's role in fear conditioning and memory consolidation may play a role in this type of social processing.

The previous examples are only a few ways in which the limbic system is involved in complex cognitions and behaviors. Because we use emotion, learning, and memory so extensively, the roles of the limbic system are essentially limitless.

Moving Forward

While the notion of the limbic system has spurred a variety of important scientific experiments aiming to uncover the neural correlates of emotional behavior, learning, and memory, the limbic system remains an enigma to many scientists. As reflected above, one major problem in the conceptualization of the limbic system is its inherent lack of clearly defined boundaries between limbic and nonlimbic forebrain regions. While the limbic system was first described as the emotional system of the brain, recent research on the functions of limbic structures has led to an understanding that the system is much more complex and elusive than originally construed. Though limbic system structures do play a large role in emotional processing, they also have many other functional identities. As such, the limbic system should not be conceptualized as a functionally complete unit. In fact, no single functional grouping of the brain should be considered independent. It should never be forgotten that the brain is constantly using its countless networks of billions of neurons to work together to accomplish specific goals. While the unclear boundaries of the limbic system have created problems for scientists, the use of the term 'limbic system' may not be completely obsolete, as long as it is understood that any area of the brain may have some degree of limbic involvement (as it may have involvement in any brain system) at certain times or in certain situations. The role of the limbic system adapts to the needs of the organism at any given time, and the degree to which different brain regions are involved with the limbic system also adjust to ensure that all of the brain's systems operate together as a harmonious whole.

Abstract

This article explores the concept of 'liminality,' tracing its development from the work of the French ethnologist Arnold van Gennep, to the pioneering theoretical anthropology of Victor Turner, and goes on to consider ways that ideas of liminality have informed more recent discussions and debates, particularly in relation to the anthropology of experience, tourism and mobility, and place and space. Arguing that what is understood by 'liminality' today encompasses a wide array of meanings and theoretical associations, the article examines the extent to which the concept finds resonance with a rich and diverse field of social, cultural, and geographical enquiry.

The concept of 'liminality,' much like the phenomena to which it is generally held to ascribe, is itself passing through something of a transitional phase. From its origins in the work of the French ethnologist Arnold van Gennep, through to the pioneering theoretical anthropology of Victor Turner in the 1960s and 1970s, what is understood by the term liminality today encompasses a wide array of meanings and theoretical associations that go far beyond those more traditionally linked with anthropological discussions on ritual, performance, pilgrimage and cross-societal 'rites of passage.' As Meethan (2012: p. 69) notes, the concept can be found in studies on management, health, education, cyber space, governance, sexuality, and tourism, to name but a few. One of the foremost points of critical intersection that has propelled renewed interest in liminality and liminal phenomena in recent years is the relationship between liminality and place and space. Indeed, those surveying the abundant literature on border zones, nonplaces, interstitial spaces, edgelands, contact zones, spaces of hybridity, third space, heterotopias, and so on, could be forgiven for thinking that liminality is and ever has been intrinsically spatial in terms of the discursive landscapes within which discussions on liminality are invariably situated.

While undoubtedly such trends can in part be attributed to the impact of a much broader 'spatial turn' (Warf and Arias, 2009) that has left its mark on social and cultural theory in recent decades, it can also be taken as evidence of a concerted push to reengage with the concept of liminality in ways that acknowledge, but which at the same time are by no means bound by the foundational work of figures such as van Gennep and Turner. As Thomassen (2009) notes, the concept has 'traveled' since it was first introduced in van Gennep's influential book *Rites de passage*. Accordingly, in the following text the authors set out some of the important theoretical background to liminality, acknowledging that van Gennep himself has often remained a marginal figure in the intellectual history of a concept that was to become so indelibly linked with the work of Turner. The authors then turn to some of the ways that liminality can more productively be understood in relation to wider discursive fields to which it is affiliated or into which it has encroached, particularly those that cluster under the rubric of the anthropology of experience, tourism and mobility, emotions and the self, and those linked to discussions of landscape, place and space. Given the more diffuse theoretical terrain that has come to frame discussions of liminality and liminal phenomena, and the attendant difficulties this can bring with it in terms of clearly delineating the meanings and practices that potentially fall under its banner, there is, as the authors have argued elsewhere (Andrews and Roberts, 2012), a need to rethink and 'remap' liminality. As the cartographic reference here alludes, this is a process which has most notably sought not only to explore the constitutive spatialities of liminality, but also to examine the different ways, and the extent to which, 'in-between spaces' can be said to represent one of the defining characteristics of modern topographies of self and society.

Arnold van Gennep

What the authors have come to understand as liminality in relation to social and cultural practices stems in no small part from the work of Arnold van Gennep (1873–1957), whose *Rites de passage* was published in 1909, but not translated into English until 1960. Measured against the legacy of sociological and anthropological 'founding fathers' such as Emile Durkheim, van Gennep's body of work has remained on the periphery of theory and debate (Thomassen, 2009: p. 7). With an impressive 437 titles in his bibliography, van Gennep, who mastered 18 different languages (Thomassen, 2009: p. 8), published on a wide range of topics but it is his work on liminality that has by far proved the most influential.

Derived from the Latin word for 'threshold' (*limen*) – an etymological reminder of the important spatial underpinnings to the concept – for van Gennep, 'liminal' is more directly related to the symbolic processes and ritual conventions that structure and define key moments of social transition, or 'rites of passage.' His research examined the relationship between liminal experiences and lasting effects of those experiences, arguing that structure/order is derived from liminality – from the crucial middle or 'in-between' states that facilitate ritual passage from one social stage to another. For van Gennep,

liminality does not presuppose certainty or offer an explanatory causality with regard to outcome, but rather describes a world of contingency "where … 'reality' itself, can be carried in different directions" (Thomassen, 2009: p. 5). Liminality is thus a means to conceptualize the moments between structure and agency: "in liminality, the very distinction between structure and agency ceases to make meaning; and yet, in the hyper-reality of agency in liminality, structuration takes place" (Thomassen, 2009: p. 5).

As elaborated by van Gennep, rites of passage form an explanatory codification or analytical tool by which to understand all rites and his work distinguishes between different types of ritual, ranging from change in status to those that mark the passage of time. Rites of passage become a special category with three subcategories: separation, transition (the liminal phase), and reincorporation (the postliminal stage). Basing his analysis on existing empirical and ethnographic data, van Gennep observed a pattern in rituals that he argued is universal and replicable across cultures and societies (Thomassen, 2009: p. 6). Celebrations or initiations are important features of social rites of passage that are classified into four types of social movement:

1. The passage of people from one status to another, e.g., marriage (moving from fiancée to wife or husband), initiation ceremonies in which the outsider of a group becomes an insider.
2. The passage from one place to another, e.g., moving home.
3. The passage from one situation to another, e.g., starting a new job, school, joining university.
4. The passage of time – typically the passage of a whole social group moving from one period to another, e.g., New Year, New Government or Ruling authority (King/Queen/Emperor) (see Andrews and Leopold, 2013: p. 36).

van Gennep's analysis identified certain characteristic patterns that occurred in the order of the ceremonies:

- Separation/preliminal – the physical detachment of the participant from normal life. As Gunnell (2007) observes of Busar initiation traditions in Icelandic Gymnasia, new pupils are only allowed to walk along marked pathways which separate them from the spaces of movement used by the rest of the school's students and teachers.
- Liminal/transitional – the most important period according to Victor Turner in which the participant is literally and symbolically marginalized. During this time, the participants in the ritual have a sense of *Communitas*. Communitas – a concept later developed by Turner (1969) – is a feeling of camaraderie between those who are the focus of the ritual. Gunnell's (2007) study again proves useful here as the new pupils are argued to feel a sense of bonding with each other as they share the same ordeals – wearing odd clothes and participating in rituals – before they become fully accepted into the life of the school.
- Incorporation/postliminal – the participant is reincorporated into society/returned to society. In Gunnell's Icelandic example this occurs when, having completed their challenges, the new pupils are finally accepted into the life of the school, which is celebrated with a meal or dance (see Andrews and Leopold, 2013: p. 36).

Melford Weiss's 1967 article 'Rebirth in the Airborne' applies van Gennep's tripartite model of liminality to the training and initiation rituals involved in becoming an American paratrooper. As part of their training, trainees are separated from and discouraged from association with those in the outside world. The liminal phase is typically accompanied by the use of lucky charms and totems, and, in an inversion of normal social experience, initiates are subjected to continuous periods of anxiety and stress, which helps bind them together as a group and helps inform feelings of communitas. Lastly, reincorporation, which includes the playing of the national anthem and the reciting of scriptures, culminates in the 'prop blast,' a ceremonial rebirth in which initiates reenact their jump in front of the flight sergeant, and the ritual drinking of 'blast juice,' which is quaffed within the count of '1000, 2000, 3000,' the time between an actual jump from a plane and the opening of the parachute. On successful completion, the initiate is ritually joined with his fellow paratroopers. Although paratrooper training is an essentially secular affair, "certain superstitious practices which are interwoven show that, in the broadest sense, it is also a religious rite" (Weiss, 1967: p. 24).

Building on ideas van Gennep outlined in *Rites de passage*, Turner argued that each rite of passage has these elements (separation – transition – reincorporation) within it, although some may be more developed than others depending on the purpose of the rite. In a funeral, for example, rites of separation, would be more pronounced than those typically associated with a wedding or graduation ceremony.

Victor Turner

As previously noted, van Gennep's ideas were developed most notably by the British social anthropologist Victor Turner (1920–83). In particular, Turner explored the concept of liminality that van Gennep had developed in relation to both the 'middle' phases of all rites and especially to rites of transition. Turner's first published work drawing on van Gennep's theory was an article on Ndembu circumcision ritual (1962). The Ndembu tribe of Zambia was the main focus of Turner's early work on ritual and the role of symbols in social processes, which he went on to develop more fully in *The Forest of Symbols*, published in 1967. For Turner, liminality is constituted in a condition or happenstance that has attributes of doubt and lack of inevitability between what is known and has gone before and future outcomes. The particular importance of Turner's work is its focus on the creative potential of ritual. In so doing, Turner put emphasis on the liminal phase connecting rites with notions of performance and investigating rites as times of suspension during which the way forward is characterized in terms of possibility and becoming. During the liminal phase of a ritual, initiates are in a 'betwixt and between' status, a threshold from which a new identity or social status can emerge. They, therefore, have the possibility to change from their former, preritual status into something different when they are reincorporated back into the everyday social world.

Turner became aware of van Gennep's work on ritual and liminality following the publication of the English translation of

Rites de passage in 1960. As one of the main proponents of van Gennep's theory, Turner played a pivotal role in drawing it to wider attention amongst anthropologists and others. Thomassen (2009: p. 14) argues that Turner discovered the work experientially, as the anthropologist was himself, at that time, betwixt and between academic posts at Manchester and the United States. This important transitional period would become manifest in the Chapter 'Betwixt and Between: the Liminal period in rites of passage,' in *Forest of Symbols* (1967). As Thomassen (2009) notes, Turner argued against the Durkheimian view that rituals mirror the dominant social order. Turner had already introduced the idea of 'social drama' in his work and found that van Gennep's formulations on rites of passage sat well alongside the idea. Turner (1982: p. 27) argued that during the liminal phase of rituals, play is often involved: "Liminality may involve a complex sequence of episodes in sacred space-time, and may also include subversive and ludic (or playful) events … in liminality people 'play' with the elements of the familiar and defamiliarize them." With this emphasis on playful action, liminality becomes significant in understanding individual and group responses to the 'betwixt and between' rather than emphasizing only its role as part of a sequence of events. For Turner, the liminal phase presents the opportunity of being reshaped or 'fashioned anew' (1969: p. 81) in which the persons at the center of the experience are prepared for and embody their new statuses. In short, liminal experiences shape personality, focus mind and experience, and foreground human agency (Thomassen, 2009: p. 14). Drawing on the work of philosophers such as Dilthey, the emphasis on experience and performance would become key elements in Turner's writings on liminality and liminal phenomena (see Section Liminality and Anthropology of Experience).

In *The Ritual Process*, Turner argues that the period of liminality or liminal people (that is people on the threshold of becoming different) 'are necessarily ambiguous' (1969: p. 81) defying classification in terms of the world of the everyday: "liminal entities are neither here nor there; they are betwixt and between the positions assigned and arrayed by law, custom, convention, and ceremonial" (1969: p. 81). The 'threshold' people Turner describes are typically stripped of property or clothing which would mark their rank or status in the liminal phase making them indistinguishable from others who are sharing that experience.

A particularly notable innovation in Turner's theoretical updating of van Gennep's earlier ideas is the distinction he makes between liminal and 'liminoid.' Turner (1982) suggests that in modern consumerist societies in which work and play are more clearly defined than in traditional societies the possibilities for liminal experiences to arise are reduced, being supplanted mainly by liminoid moments found in artistic performances and the practices of leisure consumption. The ritual and experiential liminal characteristics ascribed to so-called traditional societies are transmuted into liminoid experiences through play, creativity, drama, and their associated art forms, such as theater and literature. Although perhaps based on too basic a distinction between traditional and nontraditional, Turner's concept of the liminoid allows for a more qualified or conditional sense of the liminal insofar as it defines a transitional moment that is optional and which does not involve a change of status or offer a resolution (Thomassen, 2009: p. 15). The playfulness and experiential qualities of liminoid phenomena can be transformative but they are not transitional in the same way that a rite of passage represents a liminal state of 'betwixt and between.' In 'From Ritual to Theatre: The Human Seriousness of Play' (1982), Turner notes that 'oid' derives from the Greek word *eidos*, meaning a form or shape. Liminoid thus takes the form of or resembles but is not the same as the liminal. It represents "an independent domain of creative activity" (1982: p. 33). Thus Turner argued theoretical and experimental science is liminoid as it is conducted in or 'privileged areas' (laboratories or studies) separate from society in general and issues of central political concern: "Universities, institutes, colleges, etc., are 'liminoid' settings for all kinds of freewheeling, experimental cognitive behavior as well as forms of symbolic action, resembling some found in tribal society, like 'rushing' and 'pledging' ceremonies in American college fraternity and society houses" (1982: p. 33).

The distinction between pilgrimage and tourism as, respectively, forms of liminal and liminoid ritual is one that has generated discussion in anthropological studies of tourism (see below), where the distinction is at times difficult to draw. Graburn (1989), for example, has argued that tourism is a form of pilgrimage in that the experience is that of a liminal rite of passage. Pilgrimage, a focus of some of Turner's later work with his wife Edith on liminality and ritual (1978), entails an equaling out of participants: status hierarchies are temporarily suspended and the pilgrims share a common experience of communitas, building on ideas developed in Turner's (1969) earlier work. Similar arguments have been made in respect of rave, dance, and techno cultures and subcultures (see, for example, Gerard, 2004; St. John, 2008), prompting debate as to whether these represent liminal or liminoid experiences of transition and communitas.

An important but often overlooked characteristic of the liminal phase is its association with danger. The attendant risk attached to the entering of a liminal phase or liminal space is of losing a stable sense of self and identity, or of not being reincorporated into the social world in ways that had been anticipated or desired. For those seeking drug-induced and consciousness-altering experiences of communitas, for example, the psychological and physical impacts may have permanent or long-term consequences that take the experience outside of the temporary and otherwise contained environment of the liminal phase. Death itself is also strongly associated with liminality (see Das, 1977). Lastly, the suspended nature of social life normally associated with the state of liminality can become permanent in circumstances where it is institutionalized and incorporated into dominant social and political structures of power (Thomassen, 2009: p. 22).

Liminality, Place, and Space

In his account of a walk along an ancient and notoriously hazardous tidal path situated off the Essex coast, the writer Robert Macfarlane observes, "[w]e lack – we need – a term for those places where one experiences a 'transition' from a known landscape … [to] somewhere we feel and think significantly

differently. I have for some time been imagining such transitions as 'border crossings.' These borders do not correspond to national boundaries, and papers and documents are unrequired at them. Their traverse is generally unbiddable, and no reliable map exists of their routes and outlines" (2012: p. 78).

Although he does not use the term, in this quotation Macfarlane succinctly outlines some of the defining characteristics of a liminal landscape and experience. Liminality is of inferential significance here insofar as it is 'located' both in terms of its geography and its constitutive temporality. To experience the transition, Macfarlane describes entails a process of traversing space, whether real (the physical landscape as a site of wayfinding or pilgrimage) and/or imagined (the social, symbolic, and textual spaces of transition that invest the landscape with meaning). It is also an experience that has duration: it unfolds over a period of time. But crucially, like the landscape itself, the 'routes and outlines' that otherwise order and rationalize time are – experientially at least – difficult to 'map' or reliably navigate. The pilgrim or wayfarer enters 'another place,' which, like artist Anthony Gormley's installation of the same name located on Crosby beach near Liverpool (Andrews, 2012), is governed by the contingent workings of the natural elements. By the same token, the quintessential liminality of the spatiotemporal moment is marked by the threat of danger. In the case of the tidal mudflats that Macfarlane describes this, of course, has very obvious connotations. But the extent to which borders and boundaries are elusive and 'unbiddable' may also invoke fears rooted in an incipient sense of existential or ontological displacement. In the same way, the initiate entering the liminal phase of a social ritual may experience the undoing of a fixed or habituated sense of selfhood, the navigator of liminal landscapes potentially 'crosses over' to states of being or consciousness that draw their precarious affectivity from the uncertain and 'unmappable' geographies that are temporally inhabited.

That these transitional spaces might represent 'border crossings' both highlights the structural and experiential liminality of border zones and hints at ways in which liminal landscapes do not necessarily correlate with conventional territorial understandings of borders such as those that relate to national boundaries. Border zones, like all liminal phenomena, are ambivalent in that they are at once spaces of mobility and immobility, transition and stasis (Roberts, 2002), hope and violence (Harvey, 2000), place and nonplace (Augé, 1995), memory and oblivion (Augé, 2004): spaces where the 'play' of horizons and frontiers (Marin, 1984) reflects the differential power relations that govern the increasingly complex patterns of transnational mobility. As spaces of 'radical openness' (Hooks, 1990), border zones can engender what Gloria Anzaldúa has described as a 'mestiza consciousness,' a consciousness of the borderlands that is the "product of the transfer of the cultural and spiritual values of one group to another" (1987: p. 78). Equally they may take the form of 'smooth spaces' of flow, the domain of the deterritorialized 'nomad,' the figurative (and often romanticized) embodiment of postmodern homelessness who, at home everywhere and nowhere, exists in a constant state of flux and becoming. For the nomad, the border (geographical or metaphorical) represents an otherwise striated space of power that is there to be crossed or 'smoothed out' (Deleuze and Guattari, 1986; Braidotti, 1994). The idea that these and other liminal zones are antiessentialist spaces where identities are contingent, malleable, and fluid, is one that also underpins Bhabha's concept of 'third space,' conceived of as a cultural space where hybrid identities are negotiated and forged, often in resistance to hegemonic power structures. For Bhabha, "[t]he non-synchronous temporality of global and national cultures opens up a cultural space – a third space – where the negotiation of incommensurable differences creates a tension peculiar to borderline existences" (1994: p. 218).

Although concepts such as 'third space,' 'nomad,' and *la mestiza* are predicated on a radically deessentialized space of liminal encounter, arguably they are only able to sustain their deterritorializing logic through a concomitant essentialization of space. As Smith and Katz have commented, "an absolutist spatial ontology … provides the missing foundation for everything else in flux" (1993: p. 79). By reducing the complexities and dynamics of social space (Lefebvre, 1991) to a largely rhetorical space of flow, hybridity and becoming the extent to which identities are caught within – and often at the mercy of – material and economic geographies of transnational liminality can be overlooked. An instructive and tragic case in point is that of the 23 Chinese migrant workers who drowned while picking cockles in the vast expanse of sandflats and mudflats at Morecambe Bay in 2004. Located on the northwest coast of England in Lancashire, Morecambe Bay is notorious for its fast moving tides and treacherous quicksand, as well as its lucrative cockle beds. Despite the dangers posed by this stretch of coastline, the Bay has long attracted itinerant workers, many of whom, as with the Chinese cockle pickers, remain at the mercy of exploitative and illegal gangmasters. While the Morecambe Bay incident brought to light the appalling conditions faced by these migrant workers, it also forced an awareness of the extent to which such groups are an invisible but immutable presence, occupying a ghostly liminal zone on the social and geographic margins of the nation; caught in the interstices of transnational space.

Situated 'betwixt and between' land and sea, Morecambe Bay Sands represent an ambiguous, and thus potentially dangerous zone on account of its unbiddable and 'unmappable' physical terrain. But, as the 2004 incident made clear, such landscapes are also liminal to the extent that they are heterotopias, or spaces of otherness, "juxtaposing in a single real place several spaces, several sites that are in themselves incompatible" (Foucault, 1986: p. 25; Hetherington, 1997). As a space of transnational migrant labor and increasingly globalized social, cultural, and economic relations, coastal resorts such as Morecambe Bay expose the underlying tensions and social divisions between representations that play on the ludic, touristic heritage of these resorts and those which address the marginality and exclusion that characterize the other set of mobilities and meanings evoked by these spaces. In this instance, the precarious and unnavigable natural landscape of Morecambe Sands becomes a metonym for the increasingly destabilizing landscapes of global capitalism. Compare this example with the hybrid spaces depicted in the film *Bhaji on the Beach* (dir: Gurinder Chadha, 1993), in which a group of British-Asian women go on a day trip to Blackpool, also on the Lancashire coast. The sense of

shared communitas and identity that the beachscape connotes in the latter stands in stark contrast to the fear, exploitation, and uncertainty experienced by those occupying very different spaces of marginality and transnational liminality in twenty-first century Britain.

Liminality and Psychotherapy

When planning his walk across Maplin Sands on the Thames Estuary (see above), Robert Macfarlane initially and very sensibly sought the services of a guide who had the detailed local knowledge necessary to navigate the route safely. Wayfarers crossing the sandflats of Morecambe Bay are also encouraged to only undertake the walk with the accompaniment of a guide. An official guide, known as the Sandpilot of Morecambe Bay, regularly leads parties on the 6-mile trek across the sands. As the authors have elsewhere noted (Andrews and Roberts, 2012: p. 8), the role of the guide highlights another common attribute of liminal landscapes in that initiates are required to place their trust in the knowledge of a 'ritual elder' or 'master of ceremonies' so as to ensure safe navigation and transit. Analogies here can be drawn with the relationship between psychotherapist and patient, the former often held to be providing a form of 'ritual leadership' (Moore, 1991: p. 25). In *From Ritual to Theatre*, Turner casts the experimental theater director Jerzy Grotowski in the role of ritual guide-cum-psychotherapist: "Let us create a liminal space-time 'pod' or pilgrimage centre, [Grotowski] seems to be saying, where human beings may be disciplined and discipline themselves to strip off the false personae stifling the individual within" (1982: p. 120). It is important to note, however, that the ritual leader is not the master or controller of transformative space. Such space "cannot be commanded – it can only be invoked" (Moore, 1991: p. 27). As such, liminality "is always within a context of containment in which the boundaries are not tended by the ego of the individual involved" (Moore, 1991: p. 29), but nor, by the same token, are they overly determined by the intervention of the leader or guide.

Navigating the psycholiminal landscapes of the patient, the therapist, like the Sandpilot, is responsible for ensuring the careful stewardship of the boundary beyond which safe and secure transformation cannot be assured. Stressing the importance of the boundary in an article examining the psychoanalyst as ritual elder, Moore argues that:

> when sensing the need for a liminal space, [individuals] will seek out boundary and containment wherever they can. If knowledgeable ritual elders are not present to invoke liminal space and lead them through it, then they gravitate to the liminoid and try to find containment or generate it on their own. The attraction of geographical boundaries such as seashores to those in transition states is a striking example of this intuitive quest for the boundary. Finding a natural boundary is, of course, relatively simple. Locating an appropriate transformative container, however, is much more difficult. (1991: p. 28)

The concepts of liminal and liminoid, and particularly the work of Turner, have been influential in the development of Jungian-based psychoanalysis in which the therapeutic contract between therapist and client is conceived of as a ritual process. The edited collection 'Liminality and Transitional Phenomena' (Schwartz-Salant and Stein, 1991) brings together work by scholars of psychology and religion alongside that of psychotherapists and counselors who all approach the theory and practice of Jungian psychotherapy by engaging closely with ideas of liminality. The importance of the 'container' or 'vessel' as part of the psychotherapeutic ritual process is one that several contributors draw attention to. Hopcke, for example, notes that the concept of liminality is 'felicitously consonant' with Carl Jung's own approach to analysis, which was to provide a space, "a temenos, a magic circle, a vessel, in which the transformation inherent in the patient's condition would be allowed to take place" (1991: p. 117). For Hopcke, liminality is the very essence of effective analytic work, the aim of which is transformation and change.

Liminality and Tourism

The concept of liminality has found its way into more areas of academic enquiry through its use in tourism. In the first place, the idea that tourism marks some form of hiatus in the (yearly) life was expounded in the early days of the anthropological study of tourism in Nelson Graburn's text *Tourism as a Sacred Journey* (1989 [1976]). In this work, Graburn follows van Gennep's formulation of *rites de passage* to understand the touristic experience as a leaving of the normative world, to enter a liminal phase of separation in which the holiday experience allows for the individual to feel as if they have been renewed in some way before their return home upon which they are reincorporated back into the everyday, heavily routinized world they left behind. As part of the liminality of the vacation, the holidaymakers may feel some sense of communitas with their fellow travelers in which they share the trials and tribulations of being in an unfamiliar environment.

The ritualistic and episodic role of tourism as a period which permits different attitudes and behaviors to emerge from that found in the home world was used as a basis to understand the apparently ludic behavior of tourists in relation to their sexual conduct aboard charter tourism yachts in the Caribbean. In his study, James W. Lett Jr. (1983) argues that tourists to the British Virgin Islands treat the place as a playground that allows them to indulge in a form of 'playground culture' (1983: p. 55). The emphasis on play marks the experience as liminoid rather than liminal and draws attention to the distinctions highlighted by Turner (1982) – see above.

Another major contributor to the linking of the concept of liminality to tourism can be found in the work of Rob Shields (1991). In *Places on the Margin*, Shields notes that following the patronage of the Prince Regent, the southern English seaside town of Brighton developed from a fishing village into a seaside resort where dominant discourses could be subverted. For example, Brighton became connected with the 'dirty weekend,' often represented in the form of the 'dirty postcard.' What this referred to in practice was the conduct of illicit sexual relationships. Such was the reputation of

Brighton that it was often used to 'stage' adulterous encounters to further divorce proceedings. Shields argues that the beach took on a carnivalesque role, which allowed the transgression of propriety and societal norms and that this helped to mark it as liminal zone. In her study of charter tourists to Magaluf and Palmanova on the Mediterranean island of Mallorca, Andrews (2011) applies the concept of liminality not only to the beach but to the resorts as a whole, in which the practice of the holiday is marked out as different from the 'everyday' in the actions of the tourists and those mediating their experiences. This can be illustrated by the purchase of clothes especially for the occasion and the amplification of difference (and attendant dangers) promoted by the tour operators.

The degree to which holiday taking can be seen as markedly different from the everyday activities or out of the ordinary has been criticized (see, for example, Veijola and Jokinen, 1994). Andrews (2009) suggests that it is more of a disruption to habitus rather than a complete change per se, arguing that this line of thought can be developed further by thinking more carefully about the concept of experience and in particular the nuances of what it might mean and how it can be used.

Liminality and Anthropology of Experience

In their edited collection *The Anthropology of Experience*, Victor Turner and Edward Bruner (1986) discuss the nature of experience within a dramaturgical context of performance and narrative. In their volume the meaning of experience, as Geertz suggests, remains "the elusive master concept of this collection, one that none of the authors seems altogether happy with and none feels able to really do without" (1986: p. 374). In the English-speaking world, one of the problems encountered when trying to define or discuss experience is the limitations of having only one word of use in the English language, unlike in German, for instance, where there are two: *Erfahrung* and *Erlebnis*. *Erfahrung* refers to the idea of encounters and *Erlebnis* to the world of senses and emotions, intuition, and movement. The *Erlebnis* is not fixed, rather it is a process in which there are a number of possibilities that arise within or through a particular situation; it is the world of the subjective or of being affected by something (see Andrews, 2009). Drawing on the work of the German philosopher Wilhelm Dilthey (1833–1911) Turner argues that the liminal phase allows for "unique structures of experience (Dilthey's *Erlebnis*)" (1983: p. 41). Thus liminality provides the *Erlebnis* form of experience, which is a world of possibilities and becomings: "Liminality can perhaps be described as a fructile chaos, a storehouse of possibilities, not a random assemblage but a striving after new forms and structures, a gestation process, a fetation of modes appropriate to postliminal existence" (1983: p. 42). Turner compares this to 'ordinary' life, which is lived in the indicative mood and argues that liminality, in its abilities to offer possibilities, operates in the subjective. It is these ideas of the exploratory nature and potential of becoming in liminality that link it to the idea of social drama developed most notably by the philosopher John Dewey (1859–1952).

The link between Turner's ideas of liminality and *Erlebnis* had been explored in an earlier text *From Ritual to Theatre*, published in 1982. In this, Turner argues that an anthropology of performance is an integral part of the anthropology of experience and that performance is found in many different types of cultural expression: ritual, carnival, and theater to name but a few. Such performances are themselves processes and it is in this process that "what is normally sealed up, inaccessible to everyday observation and reasoning, in the depth of sociocultural life, is drawn forth" (1982: p. 13). The link to the idea of social drama and liminality being in the subjunctive is again clear: that such experiences allow for the emergence of a number of possibilities. This is echoed in the work of Michael Jackson in his work on existential anthropology, where experience is entwined with notions of 'being.' As Jackson observes "[b]eing is (…) in continual flux, waxing and waning according to a person's situation" (2005: p. x).

Conclusion

The concept of liminality is, as the authors have discussed, closely bound up with experience and the processes of change, transformation, and transition that individuals undergo as part of that experience. Tropes and practices of play, performance, flow, becoming, potential, gestation, passage, movement: these are all in some way constitutive elements that variously inform the essential 'in-between-ness' of liminal experiences and states. Socially, psychologically, and ontologically this in-between-ness entails a process of letting go of stable topographies of selfhood; of 'striving after new forms and structures' as Turner puts it. As a 'fructile chaos' liminality can also, therefore, be characterized in terms of danger (Thomassen, 2012) and of the anxieties and emotional turbulence that accompanies the passage through liminal states or spaces. Increasingly, however, the concept has taken on a far looser set of meanings that has at times reduced what might be understood as 'liminal' to a rather vague sense of being 'on the edge' or 'in-between' in ways that have become decoupled from the concept's attendant (and requisite) social underpinnings. Paying closer critical attention to the spatialities of liminal phenomena, an issue the authors addressed in their book *Liminal Landscapes: Travel, Experience and Spaces In-between* (Andrews and Roberts, 2012), is one of the ways that liminality can be regrounded in the foundational work of van Gennep, Turner and others, whilst at the same time acknowledging the extent to which the concept has 'traveled' and aligned itself with a far broader field of social, cultural, and geographical enquiry.

Limits to Growth

Abstract

This article reviews the findings of the 1972 report titled 'The Limits to Growth' and the debate that followed its publication. This study was one of the first attempts at quantifying how the world's economic system evolves as a function of the availability of natural resources, pollution, and population growth. The general conclusion was that the combination of resource depletion, persistent pollution, and overpopulation was likely to drive the system to economic collapse and then to a population reduction at some moment during the twenty-first century. Collapse could be avoided only by means of drastic changes in the way the world's economic system was run. The reaction to the study was initially favorable but then turned to general disbelief. At present, however, there is clear evidence of a return of interest in the study's methods and findings.

Introduction

The 1972 'Limits to Growth' (LTG) study (Meadows et al., 1972) was little less than a major scientific revolution for its times. Arriving in the general atmosphere of optimism of the years after World War II, it was the first attempt of a quantitative determination of how exactly the limits of the planet would affect the economy. The book carried a somber message: given the assumption of 'business as usual' in the way the economy was run, the collapse of the world's economic system was unavoidable as the result of a combination of resource depletion, persistent pollution, and overpopulation. The model also indicated that the human population would start declining some decades after the collapse of the industrial and agricultural systems. The study had no pretense to be able to determine when exactly would the collapse start but, using the best data available for the amounts of resources available and assuming 'business as usual,' the model indicated that the beginning of the productive decline could be expected to occur within the first two decades of the twenty-first century. The study also indicated that technological solutions that would, for instance, increase the availability of resources, could only postpone the collapse but could not prevent it. Only a radical change in the way the economy was run could stabilize the economic system throughout the twenty-first century.

The LTG study generated remarkable interest and the total number of copies sold all over the world is estimated to be more than one million (Meadows, 2010). Initially, the study generated great interest and a positive response but, in the long run it led to widespread rejection of the study's methods and results. However, there is evidence that the debate had not been exhaustive and that rejection was too hasty (see, e.g., the book 'The Limits to Growth Revisited' (Bardi, 2011). A return of interest in the LTG study is evident and it appears that its results are more and more relevant for the present situation of the world's economy.

Origins of the LTG Study

The 'LTG' was not the first study aimed at evaluating the effect of limited natural resources on the economic system. In 1866, William Stanley Jevons was perhaps the first to examine the effect of mineral depletion on the economy with his 'The Coal Question' (Jevons, 1866). Jevons surmised that the depletion of coal reserves would raise prices and gradually make coal not affordable for the British industry and that, at that point, coal production would start declining. This qualitative interpretation is perfectly compatible with the results of the LTG study, obtained more than a century later. However, in time the mainstream thought in economics moved to a more optimistic vision. A model developed by Harold Hotelling in 1931 (Hotelling, 1931) (known nowadays as 'Hotelling's rule') assumed that a 'backstop resource' would always be available to replace a depleted resource. In 1956, Robert Solow (Solow, 1956) proposed a model – later modified by Stiglitz to include the effect of mineral depletion (Stiglitz, 1974a,b) – that featured technological progress as a parameter that could always keep the economy growing. Models developed by the Austrian School of economics also emphasized technological progress as a way to overcome the depletion problem (see e.g., (Boettke, 1998) for a general description of the school, (Zimmermann, 1933) for an early assessment, (Bradley, 2004), and (Bradley, 2007) for a modern interpretation of the depletion question).

But the ancestry of LTG lies not just in economics; it can be found also in biology with the work of Alfred Lotka (Lotka, 1925) and Vito Volterra (Volterra, 1931) who laid down the foundations of quantitative studies of population dynamics. By revisiting and expanding these methods, Jay Forrester developed in the 1960s the field that became known as 'system dynamics' (Forrester, 1989). These studies were the origin of the LTG model as well as of a world modeling study developed by Forrester himself and published in 1971 with the title 'World Dynamics' (Forrester, 1971). Another study that prefigured some of the concepts later developed in the LTG study was 'The Tragedy of the Commons' by Garrett Hardin (Hardin, 1968). Hardin's study and others that followed showed that natural resources – even renewable ones – tend to be exploited in a free market economy at rates higher than their capability to reform. This tendency (termed 'overshoot' by Catton (Catton, 1982)) leads to the collapse of the production when the capital returns become insufficient to create investments in further exploitation. This concept can be seen as the basis of all the LTG results.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.91047-X

In a different field of knowledge, in 1956, the American geologist Marion King Hubbert developed an empirical model (Hubbert, 1956) that described how fast mineral resources were exploited, proposing a 'bell-shaped' production curve that, later on, became known as the 'Hubbert Curve.' This model was purely empirical, but it was later found that it could be described as a simplified version of a dynamic model (Bardi and Lavacchi, 2009). Another field that can be considered as part of the LTG ancestry is that of pollution studies. The concept had been discussed from the start of the industrial revolution and it began to be considered as a serious problem after the end of World War II, in particular as the result of the great smog crisis in London in 1952 (Davis, 2002). Shortly afterward, the book titled 'Silent Spring' written by the American biologist Rachel Carson (Carson, 1962), was the origin of the modern 'environmental movement.'

The Limits to Growth Model and Its Main Results

The LTG study examined the future by means of a model called 'World3' based on system dynamics, a method of calculation originally developed by Jay Forrester (Forrester, 1989) to describe the evolution of complex systems. The method is based on the concepts of 'stocks' and 'flows.' The first term, stocks, describes quantitative physical entities, and the second, flows, how they change in time. System dynamics models are usually implemented as a set of correlated differential equations that describe how stock sizes vary with time. Feedback effects (that is how flows depend on stock sizes) are a fundamental element of this approach (Forrester, 1994).

The model used for the LTG study contained five main stocks: (1) natural resources, (2) industrial capital, (3) agricultural capital, (4) population, and (5) pollution. The model assumed that the exploitation of mineral resources would generate more industrial capital which, in turn, would lead to more rapid exploitation, resulting in an exponential growth trend. However, the finite amount of mineral resources would gradually reduce the accumulation of capital and, eventually, depreciation would play an increasingly important role in reducing the capital stock. As a consequence, the flow of resources into the economic system would stop growing and eventually decline, generating also the decline of the industrial production. A similar mechanism was assumed to take place for renewable resources, e.g., agriculture; which could be depleted if their exploitation rate was too fast, for instance, depleting the fertile soil. Finally, the effect of growing population on the economy was taken into account assuming that population growth did enhance production but also that it would increase the problems of resource overexploitation and pollution – eventually becoming one of the major factors of the collapse of the economic system. Population growth also depended on the availability of food and services, but the dependency was not simply proportional, but rather modeled according to historical data. These parameters and their reciprocal interaction were defined and adjusted according to the available data and the model was tuned in such a way to be able to reproduce known historical trends.

The 1972 LTG study presented a set of 12 scenarios, which examined the behavior of the world's system according to various parameters in input. A robust feature of these scenarios was that the gradual depletion of mineral resources and the increasing cost of pollution tends to generate the collapse of industrial and agricultural production, followed later on by a decline in the world's population. The so-called 'base case' or 'standard run' scenario, the one that used the data judged to be the most reliable at the time, placed the start of the productive decline for some moment during the first two decades of the twenty-first century (**Figure 1**).

Other scenarios presented in the study took into account the effects of different parameters. Various hypotheses were tested; among these the availability of larger resource stocks, different sensitivity of the system to pollution and the effect of technological breakthroughs. None of these hypotheses could avoid collapse, they could only postpone it. Only a careful set of policies aimed at reducing resource consumption, fighting pollution, and stopping population growth could stabilize the system and maintain a constant level of production and population throughout the twenty-first century. Later versions of the study, (Meadows et al., 1992) (Meadows et al., 2004) updated the results of the 1972 study, but generated basically similar results.

The Scientific Discussion

After publication, in 1972, 'The LTG' was the object of a rigorous scrutiny, as it is normal for a major and innovative study. The main elements of the debate are reported in detail in later works (see, e.g., (Myrtveit, 2005) and (Bardi, 2011)). To summarize, a model that attempts to predict (or at least evaluate) the future can be judged on the basis of different criteria. A first one is based on the model's internal consistence and compatibility with what we know of the world. A second criterion consists in verifying whether the theory's predictions actually turn out to be correct. Obviously, in 1972 there was no way to judge the correctness of the LTG model by comparing it to historical data since its scenarios spanned more than one century in the future. However, a number of attempts were made to evaluate the model in terms of its internal consistency and compatibility with the general knowledge of the time.

The immediate reaction of several economists was to remark that the LTG model was not consistent with the macroeconomical models of the time. As an example, in a 2008 newspaper article, (Krugman, 2008) Paul Krugman describes this reaction in these terms (in this case, referred to the studies by the developer of system dynamics, Jay Forrester, but aimed in general also against LTG) "Forrester, an eminent professor of engineering, decided to try his hand at economics, and basically said, 'I'm going to do economics with equations! And run them on a computer! I'm sure those stupid economists have never thought of that!' And he didn't walk over to the east side of campus to ask whether, in fact, any economists ever had thought of that, and what they had learned." A number of similar reactions are reported in (Bardi, 2011).

However, critics also went more in depth in their examination. Among them, William Nordhaus published a strong criticism of Forrester's 'World Dynamics' (Forrester, 1971) that was also directed against the LTG report. In his paper, titled 'World Dynamics: Measurements without Data,' (Nordhaus,

Figure 1 Scenario for the 'base case' assumptions for the 'limits to growth' study published in 1972 Courtesy of Dennis Meadows. This figure has been scanned from the original 1972 book.

1973) Nordhaus claimed that Forrester's models were not based on historical data and attempted to prove that some of the equations of Forrester were unable to describe the behavior of the real world. In his rebuttal (Forrester et al., 1974), Forrester replied that Nordhaus had incorrectly interpreted the model and showed that its equations could indeed reproduce historical data. One of the most in-depth contemporary examination of the 1972 LTG model was performed in the book titled *Models of Doom* (Cole, 1973). The debate is reviewed in detail in (Bardi, 2011) and the author arrives at the conclusion that most of the criticism proposed by the various authors of the book was based on fundamental misunderstandings. Mainly, the criticism was based on the claim that the LTG authors had been too pessimistic in their estimates of the availability of resources and that they had ignored the possibility of technological advances to increase the resource stock. But this criticism fails because the LTG study included scenarios that considered much larger resource stocks than those available according to current data and also the effect of technological breakthroughs that would increase the efficiency of use of the existing stocks.

However, the editors of the 'Models of Doom' book, H.S.D. Cole and R.C. Curnow, also examined in depth the model of the LTG study. Both in the book and in an article published in the same year (Cole and Curnow, 1973a) they emphasized several points that they described as weaknesses of the LTG model. In particular, the inability of the model to 'simulate backwards' ('backcasting') when forced to do so (Cole and Curnow, 1973b). In this case, the LTG authors noted in their rebuttal in the same publication (Cole and Curnow, 1973b) that their model had not be designed for backcasting and that this criticism had little or no relevance to the result of simulations performed the way the model was designed to work. On this controversy, Bardi notes (Bardi, 2011) that the alleged flaws of the LTG model were minor, but that the debate could have led to an improvement of this and other system dynamics models. However, as it will be discussed later on, the scientific debate on the LTG study was soon swamped by a political quarrel that prevented further meaningful discussion.

Several years after the first flaring of this debate, a new attempt of an in-depth analysis of the LTG study was performed by William Nordhaus (Nordhaus, 1992). This study was one of the few (if any) that attempted a serious comparison of models based on system dynamics with the current models used in economics, in particular, with the 'Solow–Stiglitz' model (Stiglitz, 1974 a,b). A detailed discussion of this article and of its claims can be found in (Bardi, 2011) where the author summarizes it as follows: "What Nordhaus was really doing with his 1992 paper was to present a version of the standard neoclassical model of the economy and contrast it to the LTG model. As obvious, the two models have points in common and differ in others. Both models can describe the nearly exponential growth of the economy from the beginning of the twentieth

century, all the way to the present time. Where the two models diverge is, roughly, with the first decades of the twenty-first century. The Solow-Stiglitz model states that the economy will keep growing forever; the LTG model, instead, indicates that at some point it will reach a maximum and then start declining." Obviously, no conclusion on this point could be reached in 1992. At present, however, we are close to the dates for which some of the LTG scenarios had proposed the start of the world's economic decline. During the coming years, it will be possible to tell if these scenarios have been disproved by reality.

After 1972, only a few studies attempted to use the LTG methods for new studies of world modeling. The main exception was 'The Global 2000 report to the president of the U.S.' (Barney, 1982) requested by president Carter which, however, had very little impact. System dynamics continued to be practiced and studied for various applications dealing with physical, business, and social systems (see, for instance, the site of the System Dynamics Society, http://www.systemdynamics.org/) but world modeling tended to decline and slowly disappeared from the scientific horizon. The final blow that condemned the LTG study to oblivion was an article by Ronald Bailey that appeared on Forbes in 1989. In this article, Bailey revisited criticism that had appeared in 1972 on the New York Times (Passel et al., 1972) to accuse the LTG study of having made 'wrong predictions' stating that some mineral commodities (Gold, Mercury, copper, fossil fuels, and others) should have already run out at that time. Later on, Bailey repeated his accusations in the 1993 book titled 'Ecoscam' (Bailey, 1993). As discussed in (Bardi, 2011) these accusations are groundless: there were no such predictions in the LTG book; on the contrary, no mineral resources were supposed to 'run out' before the end of the twenty-first century. Nevertheless, Bailey's accusation had an incredible success. With the Internet era arriving, it went viral and is still popular in the Web today and was stated again, recently, in a 2013 article on 'The Australian' (Burrell, 2013).

The Political Debate

The 'LTG' study was not just an exercise in solving differential equations. It was a study with considerable political relevance. And it was not just the result of the scientific curiosity of a group of researchers, but it had been commissioned by a think tank (The Club of Rome), which had as its stated objective that of influencing governments' policies (a description of the origins and the story of the Club of Rome can be found in the book by Tapio Kanninen 'Crisis of Global Sustainability' (Kanninen, 2013)). The LTG book itself did not take any political position in a traditional sense, but it could not avoid to be interpreted through a political lens. After having presented several possible future scenarios based on 'business as usual' assumptions and concluded that all of them led to economic collapse, the authors proceeded to use their model to find conditions that could avoid economic overshoot and subsequent collapse. These included limiting the exploitation of natural resources, tight controls in industrial emissions, birth control, and more. Of course, these proposals had a strong political relevance. Giorgio Nebbia (Nebbia, 1997) and Mauricio Schoijet (Schoijet, 1999) have examined the issue and they tell us how several groups united in the rejection of the findings of the LTG book, despite their widely different ideological positions. In the Western world, the left saw the study as a threat to the working class, while the right saw it as an attack against free market and liberal policies. Many industrial lobbies saw the study as a direct threat to their business, while in many poor countries, the report was seen as an attempt to perpetuate the dominance of the rich West and maintain the wide gap between rich and poor countries. Finally, religious groups strongly objected to all proposals aimed at limiting birth rates.

To these already formidable political obstacles, we should add the question of how exactly the measures recommended by the LTG study could have been implemented. This fundamental issue was never discussed in the 1972 LTG book and only in the 'Commentary' section, written by the executive committee of the Club of Rome, we read a statement (p. 194) that says "The achievement of a harmonious state of global economic, social, and ecological equilibrium must be a joint venture based on joint conviction, with benefits for all." From this and other statements by the authors of the LTG study and prominent members of the Club of Rome (see, e.g., the book 'Before it is too Late' by A. Peccei and D. Ikeda (Peccei and Ikeda, 2008)), it is clear that the needed changes were seen as generated (and not imposed) by a concerted decision that would involve governments and other world organizations. But the lack of details in these proposals made sure that they would be misunderstood and, indeed, the Club of Rome was accused (and it is still accused) of all sorts of evil plans, including that of working at a program of selective extermination of the 'darker races' (as stated in the 1983 book by Lyndon H. LaRouche 'There are no Limits to Growth' (Larouche, 1983)). This kind of accusation even spilled to the scientific debate. For instance, in 1977, an article appeared on 'Social Studies of Science' (Golub and Townsend, 1977) where the Club of Rome and the authors of the LTG report were accused to be part of a global conspiracy aimed at creating 'a kind of fanatical military dictatorship.' If this statement could be read in a peer-reviewed international journal, one can imagine what could be read in the press at that time and, in later years, in the Web.

These considerations raise the question of whether the outcry that condemned the LTG study was spontaneous or orchestrated by special interest groups. The question is legitimate because modern analysis has discovered several cases during the twentieth and twenty-first centuries where smear campaigns were created and directed by industrial lobbies to protect their economic interests. The best known case is that of the debate on the health effects of tobacco smoking. In this case, the documents that the tobacco industry released as part of the 1998 'Master Settlement Agreement' clearly show that such a campaign was organized against by the tobacco lobby against science and scientific researchers. The story is told in detail, for instance, in two books focused on of the tobacco debate: 'Doubt is their Product' (Michaels, 2008) and 'Bending Science' (McGarity and Wagner, 2008). The same methods appear to have been used unchanged in other cases even today, for instance, against climate science and climate scientists. Details on the ongoing assault on science can be found in several recent books, including 'Merchants of Doubt,' (Oreskes

and Conway, 2010) 'Climate Cover-Up,' (Hoggan, 2009) and 'Climate Wars' (Mann, 2012). For the LTG case, we have no equivalent documentation. We can, however, note that the smear campaign against the study was based on the same methods and we may at least suspect that special interest groups played a role in it.

The Rebirth

In the 1990s, the rejection of 'The Limits to Growth' could be considered complete. The study and its methods seemed to have completely lost interest by universal agreement and to have been consigned to the dustbin of wrong science. However, with the new century, the economic crisis and the political unrest led to a gradual reconsideration of the study that went in parallel with research on the depletion of a specific resource: crude oil. This subject had been studied in depth already in the 1950 by Marion King Hubbert (Hubbert, 1956) and these early studies gave rise to a new assessment of the world's oil resources by Jean Laherrere and Colin Campbell. In their article published in 1998 (Campbell and Laherrere, 1998), they concluded that the world's conventional oil production could have reached a peak and then declined during the first decade of the twenty-first century. This global peak would later become a popular concept with the term 'peak oil' coined by Colin Campbell. It may have been this line of thought that led an oil expert, Matthew Simmons, to write the first paper of twenty-first century, which favorably reviewed the LTG study (Simmons, 2000). Several other authors favorably reexamined the 1972 LTG study (Bardi, 2011), (Myrtveit, 2005), (Gardner, 2004) (Hall and Day, 2009), (NØrgaard et al., 2010), (Heinberg, 2010). In particular, in 2008, Turner (Turner, 2008) found that the 'base case' scenario of LTG has described remarkably well the behavior of parameters such as population growth, resource depletion, and pollution during the past 30 years.

These results are in stark contrast with the negative opinion of the LTG study, which is still widespread today. The debate has been ongoing and the negative opinion on the LTG study remains probably prevalent. Nevertheless, it appears that the time is past when it was considered that the study could not even be mentioned, except to say that it was wrong. The debate is not likely to be solved very soon but, looking back at the more than 40 years that passed from the publication of the first LTG book, we can at least say that it was not so 'wrong' as many had assumed it to be.

More than all, we can say that LTG was a warning, not a prediction and – as such – it could not be really 'wrong.' Clearly, predicting the future is difficult and mistakes are always possible. But, the worst possible mistake that we can make with the future is to ignore it or to assume the recent trajectories always continue unabated. The problem of depletion that the LTG study had foreseen for the first decades of the twenty-first century seems to be here in the form of high prices of all natural resources. At the same time, the climate problem seems to be growing more and more intractable. It may be that we will soon have a chance to test whether the LTG scenarios of 1972 had really foreseen the trajectory of the economy of the real world as it has been developing during the past 40 years.

This article is reproduced from the previous edition, volume 13, pp. 88747–88881, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

The term 'linear hypothesis' is often used interchangeably with the term 'linear model.' Statistical methods using linear models are widely used in the behavioral and social sciences, e.g., regression analysis, analysis of variance, analysis of covariance, multivariate analysis, time series analysis, and spatial data analysis. Linear models provide a flexible tool for data analysis and useful approximations for more complex models. This article defines linear models, introduces the commonly used matrix notation for linear models, discusses estimation, testing, and model checking, and briefly looks at models for dependent data. It also mentions how the linear hypothesis is used in generalized linear models.

Introduction

The term 'linear hypothesis' is often used interchangeably with the term 'linear model.' Statistical methods using linear models are widely used in the behavioral and social sciences, e.g., regression analysis, analysis of variance, analysis of covariance, multivariate analysis, time series analysis, and spatial data analysis. Linear models provide a flexible tool for data analysis and useful approximations for more complex models.

A common object of linear modeling is to find the most precise linear model that explains the data, to use that model to predict future observations, and to interpret that model in the context of the data collection. Traditionally, analysis of variance models have been used to analyze data from designed experiments while regression analysis has been used to analyze data from observational studies but the techniques of both analysis methods apply to both kinds of data. See also Experimental Design: Overview and Observational Studies: Overview.

Definition

The linear hypothesis is that the mean (average) of a random observation can be written as a linear combination of some observed predictor variables. For example, Coleman et al. (1996) provides observations on various schools. The dependent variable y consists of the average verbal test score for sixth-grade students. The report also presents predictor variables. A composite measure of socioeconomic status x_1 is based on fathers' and mothers' education, family size and intactness, home items, and percent of fathers who are white collar. Staff salaries per pupil is x_2. The average score on a verbal test given to the school's teachers is x_3. Denoting different schools using the subscript i and the mean of y_i by m_i, a linear hypothesis states that for some unknown numbers (parameters) β_0, β_1, β_2, and β_3,

$$m_i = \beta_0 + \beta_1 x_{i1} + \beta_1 x_{i2} + \beta_3 x_{i3}$$

Mosteller and Tukey (1977, pp. 326, 566) and Mosteller et al. (1983, pp. 408–20) give excerpts and analysis of the data.

In other applications, the predictors only identify whether an observation is in some group. For example, in 1978 observations y_{ij} were collected on the age at which people in Albuquerque committed suicide, see Koopmans (1987, p. 409). Here i is used to identify the person's group membership (Hispanic, Native American, non-Hispanic Caucasian), and j identifies individuals within a group. The three categories are taken to be mutually exclusive for the present discussion (although the US government now allows for individuals to identify themselves with multiple races in various surveys and the decennial census). We can define group identifier predictor variables. Let δ_{1i} take the value 1 if an individual belongs to group 1 (Hispanic) and 0 otherwise, with similar predictors to identify other groups, say δ_{2i} and δ_{3i} for Native Americans and non-Hispanic Caucasians. Note that the predictor variables do not depend on the value of j identifying individuals within a group. Denoting the mean of y_{ij} by m_{ij}, a linear hypothesis states that for some unknown parameters μ, α_1, α_2, α_3,

$$m_{ij} = \mu + \alpha_1\delta_{1i} + \alpha_2\delta_{2i} + \alpha_3\delta_{3i}$$

Since two of the δs are always zero, this model is often written more succinctly as

$$m_{ij} = \mu + \alpha_i$$

A linear hypothesis is usually combined with other assumptions about the observations y. Most commonly, the assumptions are that the observations are independent, have the same (unknown) variance σ^2, and have normal (Gaussian) distributions. For the two examples, these assumptions are written

$$y_i \text{ indep. } N(m_i, \sigma^2) \text{ and } Y_{ij} \text{ indep. } N(m_{ij}, \sigma^2)$$

where for example, $N(m_i, \sigma^2)$ indicates a normal distribution with mean m_i and variance σ^2. Incorporating these additional assumptions, the linear hypothesis becomes a full-fledged linear model, traditionally written

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \varepsilon_i, \varepsilon_i \text{ indep. } N(0, \sigma^2) \quad [1]$$

and

$$y_{ij} = \mu + \alpha_i + \varepsilon_{ij}, \varepsilon_{ij} \text{ indep. } N(0, \sigma^2) \quad [2]$$

where the εs are unobservable random errors.

Both theoretical and computational work with linear hypotheses and linear models is facilitated by the use of

matrices. If $i = 1, 2, 3, 4$, the model (1) can be written as the equality of two 4×1 matrices

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix} = \begin{bmatrix} \beta_0 + \beta_1 x_{11} + \beta_2 x_{12} + \beta_3 x_{13} + \varepsilon_1 \\ \beta_0 + \beta_1 x_{21} + \beta_2 x_{22} + \beta_3 x_{33} + \varepsilon_2 \\ \beta_0 + \beta_1 x_{31} + \beta_2 x_{32} + \beta_3 x_{33} + \varepsilon_3 \\ \beta_0 + \beta_1 x_{41} + \beta_2 x_{42} + \beta_3 x_{43} + \varepsilon_4 \end{bmatrix}$$

Using properties of matrix algebra, this can be rewritten as

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix} = \begin{bmatrix} 1 x_{11} & x_{12} & x_{13} \\ 1 x_{21} & x_{22} & x_{33} \\ 1 x_{31} & x_{32} & x_{33} \\ 1 x_{41} & x_{42} & x_{43} \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix} + \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \varepsilon_4 \end{bmatrix}$$

Similarly, model (6) for $i = 1, 2, 3$, j=1, 2 can be written using δ as

$$\begin{bmatrix} y_{11} \\ y_{12} \\ y_{21} \\ y_{22} \\ y_{31} \\ y_{32} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \mu \\ \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} + \begin{bmatrix} \varepsilon_{11} \\ \varepsilon_{12} \\ \varepsilon_{21} \\ \varepsilon_{22} \\ \varepsilon_{31} \\ \varepsilon_{32} \end{bmatrix}$$

In general, a linear model is traditionally written using matrices as

$$Y = X\beta + e \qquad [3]$$

where Y is a $n \times 1$ matrix containing the observable random variables y, X is a $n \times p$ matrix containing observed predictors, β is a $p \times 1$ matrix containing unobservable parameters, and e is a $n \times 1$ matrix containing unobservable random errors. To have a full-fledged model, assumptions must be made about the distribution of e. One standard assumption is that the mean value of each element of e is 0. Denote the $n\times1$ matrix of mean (expected) values as E(e). This assumption is written

$$E(e) = 0$$

The corresponding linear hypothesis involves the mean values of the entries of Y, i.e., E(Y). The linear hypothesis is that

$$E(Y) = X\beta$$

for some matrix β. Another standard assumption about e is that the covariance matrix, the $n \times n$ matrix of variances and covariances between the ε_is or equivalently between the y_is is

$$Cov(e) = Cov(Y) = \sigma^2 I$$

where I indicates the $n \times n$ identity matrix that has 1s on the diagonal and 0 elsewhere.

An alternative way to write model (3) in terms of each y_i using some matrices is

$$y_i = x_i'\beta + \varepsilon_i$$

$i = 1, \ldots, n$ where β is as before and x_i' is the ith row of the X matrix. See also Analysis of Variance and Generalized Linear Models and Linear Hypothesis: Regression (Basics).

Estimation

The unknown parameters of the linear model are the elements of β, the βs, and the variance of an observation, σ^2; they must be estimated from the data. The β_js are generally estimated using least squares estimation. For given data Y, the least squares estimates are the values of β_j that minimize

$$\sum_{i=1}^{n} \left(y_i - x_i'\beta\right)^2 \text{ or equivalently } (Y - X\beta)'(Y - X\beta)$$

where the prime on $(Y–X\beta)'$ indicates the matrix transpose of $(Y–X\beta)$. (The transpose of a matrix turns the columns of the original matrix into the rows of a new matrix.)

Under the standard assumptions, least squares estimates have optimal statistical properties. If the ε_is are independent $N(0, \sigma^2)$, then the least squares estimates provide maximum likelihood estimates (MLEs) and minimum variance unbiased estimates (MVUEs). A MVUE is an estimate that has less variability than any other unbiased estimate. If we drop the assumption of normality but retain independence (actually 0 covariances) and equal variances, least squares estimates are best linear unbiased estimates (BLUEs). A BLUE is an estimate based on a linear combination of the observations that has less variability than any other unbiased estimate based on a linear combination of the observations.

In matrix terms, the least squares estimates, say, β, are obtained as solutions to the normal equations

$$X'X\beta = X'Y$$

Typically, in regression problems, the unique solution is

$$\widehat{\beta} = (X'X)^{-1Y}X'$$

In general, if $X'X$ is singular, so that $(X'X)^{-1}$ does not exist, an infinite number of solutions exist, giving an infinite number of least squares estimates. Any one of these estimates is just as valid as any other, but fortunately, for all practical purposes, the estimates are unique. This means that whenever a linear parameter $\lambda'\beta$ is identifiable in the model (estimable), the least squares estimate of the parameter is uniquely defined. See also Statistical Identification and Estimability and Analysis of Variance and Generalized Linear Models.

The other unknown parameter to be estimated is σ^2, the variance of an observation. To estimate the variance, first rearrange the model into

$$\varepsilon_i = y_i - x_i'\beta \text{ or } e = Y - X\beta$$

Then estimate β to get the residuals

$$\widehat{\varepsilon}_i = y_i - x_i'\widehat{\beta} \text{ or } \widehat{e} = Y - X\widehat{\beta}$$

the sum of the squared residuals is called the sum of squares error,

$$SSE = \sum_{i=1}^{n} \widehat{\varepsilon}_i^2 = \left(Y - X\widehat{\beta}\right)'\left(Y - X\widehat{\beta}\right)$$

The degrees of freedom error (dfE) is n minus the rank of the matrix X, i.e.,

$$dfE = n - r(X)$$

The rank of X is the number of free parameters that can be fitted to the model by least squares. The variance σ^2 is estimated by the mean squared error,

$$MSE = \frac{SSF}{dfE}$$

See also Estimation: Point and Interval.

Testing

The basic idea of testing is to create some model for the process of generating the data, and evaluate whether the observed data are consistent with that model. For example, such a model might be

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0, \sigma^2)$$

One can think of this model has having four parts: (a) ε_i are independent, (b) ε_i have E(ε_i)=0, i.e.,

$$E(y_i) = m_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$$

(c) ε_i have common variance σ^2, (d) ε_i are normally distributed. Data that are inconsistent with the model may occur whenever any of these four parts is inappropriate.

In the context of testing the linear hypothesis, it is assumed that these four specifications are correct and a further refinement of the model is then imposed by placing an additional restriction on

$$E(y_i) = m_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$$

The test is usually thought of as a test of this additional restriction, generally called the null hypothesis. For example, the additonal restriction could be the null hypothesis H_0: $\beta_1 = \beta_3 = 0$. In the sixth grade verbal test example, this hypothesis indicates that the variables x_1, socioeconomic status, and x_3, teachers mean verbal test score, have no ability to help predict sixth graders' mean verbal test scores. The test of whether the data are consistent with a model that incorporates $\beta_1 = \beta_3 = 0$ is based on assuming that the null hypothesis and items (a) through (d) are all correct. If assumptions (a) through (d) are correct, then data that are inconsistent with the model suggest that either $\beta_1 \neq 0$ or βor both, i.e., that the null hypothesis is not true. However, in reality, data that are inconsistent with the model can result if any of the assumptions are violated, i.e., any of the four itemized assumptions or the null hypothesis. Because of this, if one is interested in testing only the null hypothesis, it is crucial to do everything possible to validate the assumptions embodied in items (a) through (d). See also Hypothesis Testing in Statistics and Significance, Tests of.

There are two ways to think about testing a linear hypothesis. One is to think in terms of testing models and the other is to think in terms of testing parameters.

Models

In testing models one assumes the validity of a (full) model and tests to see if some smaller (reduced) model is consistent with the data. For example, with the verbal test score data a full model might be

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0, \sigma^2)$$

incorporating all three predictors. The reduced model may incorporate the idea that the socioeconomic and mean teacher verbal score variables x_{i1} and x_{i3} are not important, yielding

$$y_i = \beta_0 + \beta_2 x_{i2} + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0, \sigma^2)$$

In this context, the null hypothesis is that the reduced model provides an adequate explanation for the data. In any particular test, the full model need not incorporate all of the variables that have been measured. It need only be a model that is plausibly correct.

Both the full model and the reduced model have sums of squares error, degrees of freedom error, and mean squared errors associated with them. The reduced model is rejected as being inconsistent with the data if the following F statistic is too large,

$$F = \frac{SSR(\text{Red}) - SSE(Full)}{dfE(\text{Red}) - dfE(Full)} / MSE(Full)$$

If the reduced model is true, then both the full model and the reduced model are true, so both MSE(Red) and MSE(Full) are estimates of σ^2. It can then be shown that (SSE(Red)-SSE(Full))/(dfE(Red)-dfE(Full)) is also an estimate of σ^2, so both the numerator and the denominator of F are estimates of σ^2, and the ratio should be about 1. Of course, there is sampling variability associated with the F statistic. The theoretical F distribution describes the usual distribution of values one will encounter when making such calculations. It depends on two parameters: dfE(Red)-dfE(Full) degrees of freedom for the numerator and dfE(Full) degrees of freedom for the denominator.

On the other hand, if the reduced model is an inadequate explanation of the data, it can be shown that (SSE(Red)-SSE(Full))/(dfE(Red)-dfE(Full)) estimates σ^2 plus a positive number, so that if the reduced model is bad, the F statistic should be larger than 1. If the observed value of the F statistic is so much larger than 1 as to be inconsistent with the theoretical F distribution, one can reasonably conclude that the reduced model is an inadequate explanation of the data, i.e., one rejects the null hypothesis.

Parameters

The other way to perform tests in the linear hypothesis is to specify a null hypothesis in terms of the parameters. For example, if we assume the verbal test score model

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0, \sigma^2)$$

we might be interested in testing the null hypothesis H_0: $\beta_1 = \beta_3 = 0$ in which socioeconomic status and teachers mean verbal test score have no ability to predict. One way to test this hypothesis is to identify the reduced model associated with it, i.e.,

$$y_i = \beta_0 + 0x_{i1} + \beta_2 x_{i2} + 0x_{i3} + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0, \sigma^2)$$

Or

$$y_i = \beta_0 + \beta_2 x_{i2} + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0, \sigma^2)$$

For a more complicated example, suppose two previous studies had suggested the hypothesis H_0: $\beta_1 + \beta_3 = 5$ and $\beta_2 = 0$.

We can rewrite the hypothesis as H_0: β_1=5-β_3 and β_2=0, and create a reduced model by substitution,

$$y_i = \beta_0 + (5-\beta_3)x_{i1} + 0x_{i2} + \beta_3 x_{i3} + \varepsilon_i, \quad \varepsilon_i, \text{indep. } N(0,\sigma^2)$$

Rearranging terms gives a reduced model

$$y_i - 5x_{i1} = \beta_0 + \beta_3(x_{i3} - x_{i1}) + \varepsilon_i, \quad \varepsilon_i \text{ indep. } N(0,\sigma^2)$$

This is just a new linear model with a new dependent variable y_i−5x_{i1} and one predictor variable (x_{i3}−x_{i1}). One can compute *SSE*(Red) and *dfE*(Red) in the usual way for this new model, and simply substitute these quantities into the usual formula for the *F* statistic to get the test.

If the data are consistent with the reduced model, we have a more precise model than the one we started with. While testing provides no assurance that the reduced model is correct, the data are at least consistent with it. This more precise model can be investigated for the validity of its predictions and its usefulness in explaining the data collection process.

In addition, (estimable) parametric hypotheses can be tested directly using matrices, without identifying the reduced model. For example, the hypothesis H_0: β_1+β_3 = 5 and β_2 = 0 can be written in matrix form by creating a matrix Λ' that, when multiplied by β, isolates β_1+β_3 and β_2. The hypothesis is

$$\wedge'\beta \equiv \begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \beta_4 \end{bmatrix} = \begin{bmatrix} \beta_1 + \beta_3 \\ \beta_2 \end{bmatrix} = \begin{bmatrix} 5 \\ 0 \end{bmatrix} \equiv d$$

In matrix terms the *F* statistic for a null hypothesis H_0 : $\Lambda'\beta; = d$ is

$$F = \frac{\left(\wedge'\widehat{\beta} - d\right)'\left[\wedge'(X'X)^{-}\wedge\right]^{-}\left(\wedge'\widehat{\beta} - d\right)}{r(\wedge)MSE} \qquad [4]$$

where β is a least squares estimate of β, $r(\Lambda)$ is the rank of the matrix Λ, and A^{-} is a generalized inverse of the matrix *A*. If A^{-} exists, it is the unique generalized inverse. The reduced model test and this direct test give the same *F* statistic and use the same degrees of freedom.

Confidence regions can be constructed using the *F* distribution. For the example, we can construct a simultaneous confidence region for $\beta_1 + \beta_3$ and β_2 as follows. Let $F(0.95, r(\Lambda), n–r(X))$ be the number so that with probability 0.95

$$F = \frac{\left(\wedge'\widehat{\beta} - \wedge'\beta\right)'\left[\wedge'(X'X)^{-}\wedge\right]^{-}\left(\wedge'\widehat{\beta} - \wedge'\beta\right)}{r(\wedge)MSE} \leq F(0.95, r(\wedge), n - r(X))$$

Here, $MSE(X'X)^{-}$ is an estimate of the covariance matrix of β and $MSE[\Lambda'(X'X)^{-}\Lambda]$ is an estimate of the covariance matrix of $\Lambda'\beta$. After substituting the observed values of $\Lambda'\beta$ and *MSE* into the inequality, the only thing that is unknown in this inequality is the value of $\Lambda'\beta$. A confidence region for $\Lambda'\beta$ consists of all the values that can be substituted for $\Lambda'\beta$ while maintaining the truth of the inequality. A precise definition of the 95 percent confidence region is as the collection of all values *d* in (4) that would not be rejected by an $\alpha = 0.05$ level *F* test. If Λ' has only one row, the confidence region simplifies to a confidence interval. See also Estimation: Point and Interval.

Bayesian Estimation

An alternative to least squares estimation is Bayesian estimation. In Bayesian estimation the parameters of the linear model are considered to be random and probability distributions reflecting the investigator's prior knowledge about the parameters are specified. Using Bayes theorem, the prior probability distributions are updated into posterior distributions that reflect the information embodied in the data. All statistical inferences are then based on the posterior distributions. Sometimes, a noninformative (improper) prior is used in which case, interval estimates arrived at using Bayesian methods are numerically equal to the interval estimates obtained from classical methods, only the interpretations of the intervals change. Alternatively, real prior information is often specified by taking the prior distribution of β given σ^2 to be a multivariate normal distribution and the prior distribution of σ^2 to be an inverse gamma distribution. This leads to modified least squares estimates that are shrunk towards the mean of the prior distribution β with corresponding changes to interval estimation. See also Bayesian Statistics; Distributions, Statistical: Special and Continuous; Elicitation of Probabilities and Probability Distributions.

Model Checking

Valid testing of a null hypothesis requires that all of the four itemized assumptions embodied in the model be true. Confidence intervals and regions are collections of parameter values that cannot be rejected by tests, so they also require the validity of the basic assumptions in the model as do Bayesian and non-Bayesian estimation. Model checking is considered an integral part of all statistical inference. A variety of methods have been developed for model checking. Most are based on plotting the residuals, see Linear Hypothesis: Regression (Graphics). These methods include checking the normality assumption by plotting the ordered (standardized (Studentized)) residuals against (some approximation to) the expected order statistics of a standard normal distribution. Such a plot should be approximately linear if the data are normal.

The (standardized (Studentized)) residuals are also plotted against their corresponding predicted variables or any other variable (that does not depend on y) for which a measurement is available for each observation. In these plots, any identifiable systematic structure is an indication of problems with the assumptions.

Heteroscedasticity refers to having observations with different variances. In some models, formal tests for equal variances are available, e.g., Bartlett's test and the model-based tests discussed in Carroll and Ruppert (1988).

Lack of fit refers to the problem of having specified an incorrect linear mean structure, i.e., an incorrect linear hypothesis. Formal tests for lack of fit are often based on

identifying clusters of observations that have similar predictor variables, i.e., similar rows of the X matrix, see Christensen (1996a, Sect. 6.6). Miller et al. (1998) have provided optimal methods for grouping observations into near replicate clusters.

The independence assumption is perhaps the hardest to evaluate. If the observations are taken at equally spaced time intervals, standard time series methods are often applied to the residuals. More generally, Christensen and Bedrick (1997) proposed creating rational subgroups (clusters) of the observations in which one suspects the observations may be more similar within clusters than between clusters. The methods of near replicate lack of fit tests can then be applied to test the independence assumption.

Weighted Models and Covariance Estimation

The standard assumption in linear models is that the observations all have the same variance and that the observations are all independent. If either or both of those assumptions is invalidated, different methods of estimation and testing are required. The usual linear model has

$$Y = X\beta + e, \quad E(e) = 0, \quad Cov(e) = \sigma^2 I$$

Writing a model

$$Y = X\beta + e, \quad E(e) = 0, \quad Cov(e) = \sigma^2 V$$

where $\sigma^2 V$ is the variance–covariance matrix of the observations (and also of the unobservable errors), V can incorporate unequal variances for observations as well as correlations between observations. Assume that V has an inverse matrix V^{-1}.

Rather than using least squares estimates of β, we use weighted least squares estimates that minimize

$$(Y - X\beta)'V^{-1}(Y - X\beta)$$

for given Y and X. The estimates can be obtained by solving the normal equations

$$X'V^{-1}X\beta = X'V^{-1}Y$$

Typically, in regression problems, the unique solution is

$$\widehat{\beta} = \left(X'V^{-1}X\right)^{-1}X'CV^{-1}Y$$

These estimates are also BLUEs. Moreover, under the assumption that the observations have a multivariate normal distribution, the weighted least squares estimates are MLEs and MVUEs. The variance σ^2 is estimated by $MSE{=}SSE/dfE$ as before, except now

$$SSE = \left(Y - X\widehat{\beta}\right)'V^{-1}\left(Y - X\widehat{\beta}\right)$$

Testing a full model and a reduced model, works as before, with the F statistic still being

$$F = \frac{SSE(\text{Red}) - SSE(Full)}{dfE(\text{Red}) - dfE(Full)} / MSE(Full)$$

Note that incorporating the more general matrix V has no effect on the process of identifying reduced models—which only depend on the mean structure and not on the variance–covariance structure of the data.

All of these methods presume that V is known. In practice, V is often unknown and must be estimated from the data. This greatly complicates the entire process of data analysis. Typically, when V is estimated, weighted least squares estimates are not BLUEs or MVUEs, nor does the F statistic have an F distribution under the null hypothesis that the reduced model is true. Nonetheless, the ideas behind weighted regression are fundamental to many applications of the linear hypothesis.

A common application of weighted regression is when the observations are independent but have different variances. If the relative sizes of the variances are known, then V is known. Often the variance of each observation is modeled as a function of some predictor variables, see Carroll and Ruppert (1988).

Split plot models involve groups of observations that all have the same correlation. For example, in an experiment that involves different ways of scheduling classes in schools and different ways of assigning homework to students, the behavior of the schools might be considered independent of each other, but a group of five students taken from the same school should have similarities with each other, while being independent of students from other schools. This correlation structure must be incorporated into V. If the same number of students are measured from each school, i.e., if the groups of observations having the same correlation are all of the same size, many linear models still allow one to use least squares estimates and their associated F tests.

Mixed models involve the use of random effects, Partition X and β into two parts, so as to write

$$Y = X_1\beta_1 + X_2\beta_2 + e$$

Instead of considering β_1 and β_2 as fixed unknown parameters, treat β_2 as random. Assume that $\mathrm{E}(\beta_2) = 0$ and $\mathrm{Cov}(\beta_2) = \sigma^2 D$ with, say, e and β_2 independent. Consolidate all of the random parts into $\xi{=}X_2\beta_2{+}e$ and write a linear model

$$Y = X_1\beta_1 + \zeta, \quad E(x) = 0, \quad Cov(\xi) = \sigma^2\left(X_2 D X_2' + 1\right)$$

where $V = X_2\, DX_2' + I$. Typically, D has to be estimated. To estimate β_1, simply use the estimate of D to get an estimate of V which is then treated as the true V.

Mixed models get much more complicated. X_2 is often partitioned into submatrices $Z_1, \ldots, Z_r$ and β_2 is correspondingly partitioned into γ_k, so as to write

$$Y = X_1\beta_1 + \sum_{k=1}^{r} Z_k\gamma_k + e$$

where $\mathrm{E}(\gamma_k){=}0$, $Cov(\gamma_k) = \sigma_k^2 I$, and the γ_k are independent. The γ_k are unknown parameters, and various methods such as residual (restricted) maximum likelihood (REML) and minimum norm quadratic unbiased estimation (MINQUE) are used to estimate them. See also Hierarchical Models: Random and Fixed Effects; Longitudinal Data.

Another application of weighted estimation is in the analysis of spatial data. With spatial data, observations that are taken close together spatially are usually more correlated than observations taken far apart. V reflects the spatial correlations of the observations and X may reflect the locations of the observations. Models for V are developed based on the distances between observations. A common application in geographic information systems is map making, in which

predictions are made for a very fine grid of locations. An individual best linear unbiased predictor for an observation on the grid, say, y_0 corresponding to location x_0' is

$$\widehat{Y}_0 = x_0'\widehat{\beta} + V_{oY}V^{-1}\left(Y - X\widehat{\beta}\right)$$

where V_{0Y} is a matrix of covariances between y_0 and the original observations in Y. In practice, both V and V_{0Y} must be estimated from the data. See also Spatial Statistical Methods.

Multivariate linear models involve creating linear models for several variables at once. For example, y_{i1} might measure verbal ability and y_{i2} mathematical ability. Obviously, for any individual i, y_{i1} and y_{i2} may be correlated. The multivariate linear model fits

$$y_{i1} = x_i'\beta_1 + \varepsilon_{i1} \quad \text{and} \quad y_{i2} = x_i'\beta_2 + \varepsilon_{i2}$$

simultaneously. See also Multivariate Analysis: Discrete Variables, Overview.

Time series data involve observations $y_1, y_2, y_3, \ldots$, taken at regular time intervals. The correlation between two observations depends on the amount of time between them. One simple linear model for explaining the behavior of such data is a first order autoregression model.

$$y_i = \beta_0 + \beta_1 y_{i-1} + \varepsilon_i$$

in which the observation at time i-1 is used to predict the observation at time i. See also Time Series: General and Time Series: Arima Methods.

Generalized linear models involve transforming the mean before making the linear hypothesis. For example, if observations y_i have means m_i one might make the hypothesis that

$$\log(m_i) = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$$

This hypothesis together with assumptions about the distribution of y_i form a generalized linear model. In particular, since the linear hypothesis is based on the log transformation, this would be called a log-linear model. Parameter estimates are typically found by performing a series of weighted least squares analyses. Generalized linear models allow for the analysis of a variety of nonnormally distributed data. See also Analysis of Variance and Generalized Linear Models; Multivariate Analysis: Discrete Variables (Loglinear Models); Multivariate Analysis: Discrete Variables, Overview.

Conclusion

Models based on the linear hypothesis, and their generalizations provide tools for analyzing a wide variety of data. Linear hypotheses allow one to address numerous interesting questions about the mean structure of the data. Moreover, the models can adjust for very general forms of dependence among the data. Linear models and their generalizations continue to be the most important and widely used models for the statistical analysis of data.

Linear Hypothesis: Fallacies and Interpretive Problems (Simpson's Paradox)

DV Lindley, Minehead, UK

This article is reproduced from the previous edition, volume 13, pp. 8881–8884, © 2001, Elsevier Ltd.

Abstract

In the study of the relationship between two quantities it can happen that the relationship is seriously changed, even reversed, when a third quantity is additionally considered. This is usually known as Simpson's paradox. The article explains how the change can arise, how the true form of the relationship may be deduced, and how good experimental design can avoid the difficulty. The article is limited to situations where the relationships are linear in the expectation.

The study of relationships between two quantities has been important since earliest times: from the connection between weather and the hunted animals, down to cigarettes causing lung cancer. In the laboratory sciences it is possible to determine the relationship by controlling the conditions, changing one quantity, and observing the effect of the change on the other. In the social and behavioral sciences this determination is not possible for three, related, reasons. First, conditions can rarely be controlled. Second, it is often not possible to set a quantity at an assigned value. Third, the relationship may not be exact but possess a random element, as with the heights of parents and their children. As a result, it is not easy to determine the nature of any possible relationship between quantities. Often an apparent connection has been found, on further study, to be spurious. We begin by looking at one of the more bizarre possibilities, usually known as Simpson's paradox (Simpson, 1951), but known to earlier writers. A more recent reference is Lindley and Novick (1981). Chapter 6 of Pearl (2000) contains a fine discussion in terms of causation. It is explained using some illustrative, medical data.

Patients were given either a treatment T, or a placebo T', to alleviate a condition. After a fixed time, it was observed whether they had recovered, R, or not, R'. Table 1 gives the data in the form of a 2×2 contingency table: thus, 16 patients recovered, even with the placebo. The table also provides the marginal totals and the two recovery rates. The treatment appears to have been effective in increasing the recovery rate over the placebo by 10%. (As an aside, the numbers here are small, 80 patients in all; but the phenomenon could persist with 8000. It is not the effect of small samples that is at issue.) There is an apparent relationship between treatment and recovery, but it has a random element and outside conditions have not been controlled.

One of these conditions is the patient's sex. Table 2, in the same form, gives the data for the men who participated in the study. Again the treatment has an effect but in the opposite direction, reducing the recovery rate by 10%. Common sense might suggest that a treatment that was overall beneficial, but harmful to men, would be highly beneficial for women. The data for them can be found by subtracting the cell entries in Table 2 for men from those for all patients in Table 1. Thus, no new information is needed. The results are given in Table 3. Common sense misleads: the recovery rate for women also drops by 10% as a result of the treatment, just as with the men. This is a treatment which is bad for men, bad for women, but good for all of us. This is the paradox. It is here in an extreme form of complete reversal when an additional factor is included. It often arises in the form where there is some change in relationship when extra information is included. How can this happen?

It is easy to see what has gone wrong in the medical example. The condition is more serious for the women, with lower recovery rates than the men. Yet, the treatment has been mainly given to the men – 30 of them, against only 10 women. Perhaps the doctor was suspicious of the treatment and felt it was too dangerous to give to the susceptible women. The consequence is that overall the treatment appears beneficial because it has been mainly given to the men, who were much more likely to recover in any case than were the women. Once

Table 1

	R	R'		Rate
T	20	20	40	50%
T′	16	24	40	40%
	36	44	80	

Table 2

Males	R	R'		Rate
T	18	12	30	60%
T′	7	3	10	70%
	25	15	40	

Table 3

Females	R	R'		Rate
T	2	8	10	20%
T′	9	21	30	30%
	11	29	40	

 http://dx.doi.org/10.1016/B978-0-08-097086-8.42139-2

this is appreciated, it is clear, from the data for the two sexes separately, that the treatment is harmful. Or is it clear? Here are two considerations that raise doubts:

1. Suppose that another quantity in addition to sex is included: for example, whether the patient came from a rural or urban environment. There would then be four contingency tables: one for rural males, one for urban females, and so on. We do not give the data, but it could happen that for each of these four tables there was a 10% improvement in the recovery rate, as with the overall data in Table 1. For this to happen, the allocation of patients would need to depend heavily on sex and environment, but it could happen. Furthermore, it could happen for some factor that was unrecognized by the scientists responsible for the experiment. The lesson is that, without some care in the consideration of quantities beyond the two that are the prime object of study, it is easy to be misled about the relationship between them.
2. Suppose the numbers in the three tables remain unaltered but they apply to an agricultural, rather than medical, example. The treatment and placebo are replaced by two varieties of maize; recovery is now high yield as against low; and being male becomes growing tall as opposed to short. Thus, the phenomenon of males having a higher recovery rate than females corresponds to tall plants giving a greater proportion of high yielders. Finally, the recovery rate is replaced by the proportion of plants with a high yield. In the medical example, it was suggested that the treatment was harmful. This translates, in the agriculture case, to T' giving the better yield. Is that really right? Surely T gave the better yield (Table 1) and grew taller (Tables 2 and 3). The suggestion is that the conclusions, from the same data, are quite different in the two contexts. The reason is that, whereas the medical treatment has no influence on sex, which maize variety is grown does influence the heights of the plants. The causal patterns in the two cases are not the same.

There is another way of appreciating the distinction between the agricultural and medical examples that avoids the difficult concept of causation. Suppose, on the evidence of the tables, and no other, you had another patient with the condition: would you give them the treatment? The answer is No, because the chance of recovery for treated males is less than for males having the placebo, and similarly for females so that sex (which is outside your control) is irrelevant, and not influenced by the treatment applied. But when it comes to which variety of maize to plant, the replacement for sex, growing height, is influenced by the variety chosen. Hence the chances referred to above are irrelevant; only the chances of high yield for each variety are relevant and the growing height does not matter, since it is determined by the choice of variety. Thus T is the better maize.

Notice that in all these examples, one of the quantities, T, could be set at a chosen value. Often this is not possible and the scientist merely passively observes whether T or T' obtains. In this case, transferring from the data to a new patient, in the manner of the last paragraph, becomes even more difficult. There can be a substantial difference between observing that an event occurs and arranging that it occurs. A person who is naturally a nonsmoker can behave quite differently from one who has been pressured into giving up smoking.

In order to fully appreciate what is going on, it is necessary, as always, to argue abstractly, to escape from the contexts of medicine or agriculture, and to examine what principles are involved. This requires some mathematics and here the specific tool of probability. We write $p(A/B)$ for the probability that event A occurs, when it is known, or supposed, that event B has occurred. AB denotes the event that occurs if, and only if, both A and B occur. Then a reasonable interpretation of Table 1 is that $p(R/T) = 0.5$, $p(R/T') = 0.4$, and that T is preferred to T'. From now on, think of R, T, and M (for male) as any three events and R', T', and M' as their negations, respectively. The medical and agricultural examples provide illustrations. A third, social example with racist overtones is provided by the case, T is White (T' is Black), R is intelligent, and M is upper, social class. All data are hypothetical.

Tables 2 and 3 refer, in this abstract form, to probabilities like $p(R/TM)$, differing from those in Table 1 by the inclusion of the conditioning event M or M'. These are related to the probabilities of Table 1 by the standard results

$$p(R/T) = p(R/TM)p(M/T) + p(R/TM')p(M'/T) \qquad [1]$$

and

$$p(R/T') = p(R/T'M)p(M/T') + p(R/T'M')p(M'/T') \qquad [2]$$

These introduce two extra probabilities, $p(M/T)$ and $p(M/T')$. Table 1 compared the probabilities on the left-hand sides of the two equations. Tables 2 and 3 compared the probabilities vertically above one another on the right. Those on the left were larger in the upper equation; those on the right were smaller there. The reason for the paradox is that, on the right-hand sides of the two equations, the weights attached to those probabilities in order to combine them to produce those on the left, namely $p(M/T)$ in the upper, and $p(M/T)$ in the lower, are different. The difference was noted earlier with the treated patients being predominately male.

The paradox can be avoided if the weights are the same; namely $p(M/T) = p(M/T')$, for then any differences on the right will be reflected on the left. The general conclusion is that in studying a relationship involving T, any extraneous factor, M, should, if possible, arise with the same probability whether T is true or not. M and T should be independent. Statisticians say M is confounded with T if the probabilities are not equal. The sound recipe is to avoid confounding. Much effort has been put into designing experiments with little or no confounding.

We referred above to the difference between the medical and agricultural examples, in that the former resulted in a preference for T', and the latter for T. The reason is that in the medical case, the scientist has control over $p(M/T)$ and, in particular, can avoid confounding by having the same proportion of males among treated patients as among those receiving the placebo. With the two varieties of maize, the proportion growing tall, M, is outside the scientist's control, so $p(R/T)$ is what matters. The reader may like to consider the politically sensitive example mentioned above where the same data refer to the relative intelligences of Black and White people.

The discussion so far has referred to events occurring or not. An event can be thought of as a quantity, which takes only two

values, 1 when it occurs, 0 when it does not. The probability that it occurs is then the expectation of the quantity. Looked at from this viewpoint, probability is a special case of expectation. The ideas above, including Simpson's paradox, extend to general quantities, X, Y, and Z, replacing T, R, and M, respectively, whenever the expectations are linear, as they necessarily must be when only two numbers, 1 and 0, are involved. Suppose then that the expectation of X, given Y and Z, is linearly dependent on their values,

$$E(X/Y,Z) = \alpha + \beta Y + \gamma Z \qquad [3]$$

If, still retaining the dependence on Y, expectations are taken over Z, the result is

$$E(X/Y) = \alpha + \beta Y + \gamma E(Z/Y)$$

If $E(Z/Y)$ is also linear, equal to $\lambda + \mu Y$, then

$$E(X/Y) = \alpha' + \beta' Y \qquad [4]$$

where

$$\alpha' = \alpha + \gamma\lambda \ \textit{and} \ \beta' = \beta + \gamma\mu$$

The contrast between eqns [4] and [3] is similar to that between **Tables 1** and **2**. For example, it could happen that β was positive but β' negative. If so, eqn [3] suggests that an increase in Y would be expected to produce an increase in X. Equation [4] similarly suggests a decrease in X.

More careful analysis modifies these statements. Changing γ in eqn [3] provides a measure of the effect on X, while Z is constant. No such restraint on Z is present in eqn [4]. This is similar to Simpson's paradox, where **Tables 2** and **3** held Z, now M or $M,'$ constant, whereas **Table 1** did not. It explains the difference between the agricultural and medical examples. Z, height, cannot be held constant; whereas Z, sex, can.

It is common for eqn [3] to be included in a statement like

$$X = \alpha + \beta Y + \gamma Z + \varepsilon$$

where ε is a random error with zero mean. Similarly eqn [4] becomes

$$X = \alpha' + \beta' Y + \varepsilon'$$

Statements in this form, unlike eqns [3] and [4], disguise the fact that the real distinction between them lies in the conditions under which X is being studied. Just as with eqns [1] and [2], the important subtleties arise because of the conditions. Thus ε' hides the fact that the variation of Z is included within it, while ε does not. It is typically advantageous, when thinking about an expectation, or probability, to recognize the conditions that are assumed to hold, as well as the quantity being expected. In particular, probability depends on two arguments, not one: the uncertain event whose probability is being evaluated, and the events that are supposed to have occurred, the conditions. Distinction is sometimes made between probability and conditional probability. In reality, all probabilities are conditional. Care is needed in working with conditional expectations.

The main conclusion is that it is difficult to establish whether or not there exists a connection between two quantities and, if there does, to determine its precise form. The difficulty principally arises from the presence of other quantities that may disturb any apparent relationship. If controlled experimentation is possible, then consideration of interactions and the avoidance of confounding can be helpful in producing sound conclusions. With observational studies, in contrast, great care is necessary in avoiding inferences that the data do not fully support. An important reason why the social and behavioral sciences are less advanced than the physical ones is that controlled experimentation is more often possible in the latter than in the former.

These considerations do not deny the possibility of establishing relationships in society; merely that more care is required. Emphasis needs to be placed on other quantities and the influence they might have on the relationship. These should be measured and the data incorporated into the analysis. On the other hand, there will be factors, like height in the agricultural example, which, although influential, can be left out of the analysis. All the time it is necessary to bring to the fore the conditions under which the basic relationship obtains. In consideration of that between X and Y, it is essential to take into account Z.

Abstract

Regression analysis is the study of how a response variable depends on one or more predictors. Usually, dependence is assumed to be through the mean, and we think of the mean or regression function as describing how the mean of the response depends on the predictors. Although some regression problems can be usefully summarized using nonparametric regression methods that make a minimum of assumptions, adding a few plausible assumptions allows using parametric models for regression that give elegant and simple results. The important class of linear regression models is described in this article. These models are frequently used in practice, and can often lead to very useful results. Topics covered include both simple and multiple regression, the basic forms of the models, interpretation of estimates and parameters, testing ideas, including comparison of groups, and diagnostic methods.

Regression analysis is the study of how a response variable depends on one or more predictors, for example how crop yield changes as inputs such as amount of irrigation or type of seed are varied, or how student performance changes as factors such as class size and expenditure per pupil are varied. In this article, we present the basics of the *linear regression model*, in which (1) the dependence of the response on the predictors is through the mean and (2) the mean of the response given the predictors is a linear function of the predictors. This is probably the most important and frequently encountered regression model.

Introduction

Regression analysis is the study of *dependence*: how does a response variable change as the values of one or more predictor variables are changed? In the general case, we have a response variable y, a set of predictor variables x, and we seek to understand the *conditional distributions* given by $F(y|x)$ as the predictors x are varied. Although the study of dependence probably began even earlier, two principal ideas lead to modern regression analysis (Stigler, 1986). At the beginning of the nineteenth century, Legendre in France and Gauss in Germany studied the mean of a response as the predictors are varied using parametric models with only a few parameters. They suggested estimating the parameters by minimizing the sum of squared errors, which is the foundation for the least squares methods commonly used today. Toward the end of the nineteenth century in England, Galton, and later Pearson and Yule, provided many of the modern notions of correlation that provide a language for understanding dependence.

An example of a regression problem with one predictor is given graphically in **Figure 1**, where the response variable $y = \text{RCC}$ is the red cell count and $x = \text{LBM}$ is the lean body mass in kilograms for 202 elite athletes that trained at the Australian Institute of Sport in the early 1990s (from Cook and Weisberg, 1999). This scatterplot serves two general purposes in a regression context. First, it can help the viewer find separated or otherwise unusual points. In **Figure 1**, one of the athletes had an unusually high value of RCC, about 7, with a relatively modest value of LBM. Such separated points are often of interest in their own right, and in any case they may have substantial effects on any computed summaries. The second use for this graph is to visualize how the conditional distribution $F(\text{RCC}|\text{LBM})$ changes as the value of LBM is varied. Conditioning on LBM means looking at narrow vertical slices in the plot. The points within a slice represent approximately a sample from the distribution of RCC given that LBM is 'fixed' at the midpoint of the interval. We can visually integrate the contents of many slices to summarize changes in conditional distributions as we move from left to right. In **Figure 1**, for example, we can see that the *mean function*, $E(\text{RCC}|\text{LBM})$ that joins the mean in each slice appears to increase as we move from left to right, and furthermore that the increase appears to be approximately the same for all values of LBM. In addition, we have enough points to say something about the conditional variability by examining the *variance function* $\text{Var}(\text{RCC}|\text{LBM})$. The variability appears to be approximately the same across the plot, or apparently $\text{Var}(\text{RCC}|\text{LBM} = 50) \approx \text{Var}(\text{RCC}|\text{LBM} = 80)$, or any other value.

Figure 1 Scatterplot for the regression of RCC on LBM.

Simple Linear Regression

The simple linear regression model makes assumptions concerning both the mean function $E(y|x)$ and the variance function. In particular, we assume that for some transformation $u = u(x)$, we can write

$$E(y|u) = \beta_0 + \beta_1 u \qquad [1]$$

This equation requires some careful explanation. First, following Cook and Weisberg (1999), we allow the predictor x to be replaced by any monotonic transformation of it, such as the logarithmic, or inverse transformation. Doing so considerably expands the range of problems that can be handled using simple regression. Given this transformation, eqn [1] says that the expected increase in y for a unit increase in u is always equal to β_1 units, regardless of the initial value of u. Thus in a graph of y vs u, the mean function specified by eqn [1] is a straight line with intercept β_0 and slope β_1.

The mean function of eqn [1] concerns average behavior, but says nothing about the variation. Suppose we have observed data (x_i, y_i), $i = 1, \ldots, n$, observed on n units, and suppose further that we have computed $u_i = u(x_i)$ for the known transformation u. Of course the points (u_i, y_i) will not fall exactly on the line (they certainly do not do so in Figure 1). The unobservable differences

$$\varepsilon_i = y_i - E(y_i|u_i)$$

are called *errors*. By construction, if the model is correct the errors are random variables with mean zero and variance given by a positive constant σ^2. This amounts to assuming that the variance function $\mathrm{Var}(y|x)$ is constant. We assume that the ε_i are independent random variables. They are often assumed to be normally distributed, but the normality assumption is required only for inference, not for estimation.

The model given by eqn [1] and the assumptions concerning variability just described greatly simplify the regression problem by reducing the mean function to only two parameters, and the variance function to only one parameter. When this model is appropriate, it gives a very elegant summary to a regression problem.

Fitting

The most common method of estimating the unknown parameters in eqn [1] based on data uses ordinary least squares. Find the values $\widehat{\beta}_0$ and $\widehat{\beta}_1$ of (β_0, β_1) that minimize the residual sum of squares function $\mathrm{RSS}(\beta_0, \beta_1)$, given by

$$\mathrm{RSS}(\beta_0, \beta_1) = \sum_{i=1}^{n} (y_i - \mathrm{fit}_i)^2 \qquad [2]$$

where $\mathrm{fit} = \beta_0 + \beta_1 u_i$. Finding the estimates is an elementary calculus problem, and in general the estimates are unique and are given by a formula. The estimate of σ^2 is just $\widehat{\sigma}^2 = \mathrm{RSS}/n - 2$, where RSS is the value of the residual sum of squares function evaluated at the estimates, and $n - 2$ is the degrees of freedom, which is equal to the number of observations n minus the number of parameters estimated in the mean function, which is 2 for simple linear regression in eqn [1].

Table 1 gives typical computer output for fitting the simple linear regression model to the athletes data. The column marked Estimate gives the estimated coefficients, so the intercept is estimated to be about 3.47. The estimated slope of 0.019 suggests that we expect RCC to increase on the average by about 0.019 units for each 1 kg increase in LBM. The column marked Std. error gives the estimated standard errors of these values, which are computed as $\widehat{\sigma}$ a times a constant that depends on the values of the u_i but not on the response. The t-values are the ratio of the estimate to its standard error. These are appropriate test statistics for the hypotheses that each of the coefficients in turn is equal to zero. Assuming normal errors, these values can be compared with the t_{n-2} distribution to get significance levels. In the athletes data, tests concerning the intercept are of little interest. The test that the slope is equal to zero vs the general alternative has value $t = 9.34$ and a corresponding tiny significance level, suggesting clearly that RCC increases with LBM.

Table 1 Simple linear regression of RCC on LBM

	Coefficient estimates		
Label	*Estimate*	*Std. error*	*t-value*
Constant	3.46616	0.136820	25.334
LBM	0.0193060	0.00206768	9.337
R squared		0.303574	
Sigma hat		0.383145	
Number of cases		202	
Degrees of freedom		200	

A common summary statistic for the fit of a regression is the quantity R^2, which is defined to be the *fraction of the variability in the response explained by the model*, so

$$R^2 = \frac{\mathrm{SYY} - \mathrm{RSS}}{\mathrm{SYY}} \qquad [3]$$

where $\mathrm{SYY} = E(y_i - \overline{y})^2$ is the total variability in the response ignoring the predictors. If $R^2 = 1$, then $\mathrm{RSS} = 0$ and the mean function matches the data perfectly. If $R^2 = 0$, then $\mathrm{SYY} = \mathrm{RSS}$, and knowledge of the predictors tells us nothing about the response. For the athletes data, $R^2 = 0.30$, so about 30% of the variability in RCC is explained by LBM. R^2 is a most appropriate measure when the corresponding scatterplot appears to be an elliptical swarm of points which in turn suggests bivariate normality of both the response and the predictor. This is a very strong assumption that appears to be appropriate for this example.

Diagnostics

The residuals are defined to be the differences between the observed values y_i and the fitted values $\widehat{y}_i = \widehat{\beta}_0 + \widehat{\beta}_1 u_i$, so $e_i - y_i - \widehat{y}_i$. Unlike the errors ε_t, the residuals e_i are observable, and so they can be used in graphs and other procedures as a check on the assumptions of the fitted model. Imagine drawing a scatterplot of the residuals vs u. If the model is correct, then we should expect that the conditional distribution of $e|u$ should be the same as we move from left to right: the mean function should be constant and the variance function should be constant. If the model is not correct, then either of these two characteristics may not hold. The residual plot for the athletes data is shown in Figure 2. As one would have expected,

Figure 2 Residual plot from simple regression of RCC on LBM.

Figure 3 Regression of RCC on LBM controlling for gender. Points for females are marked with a X and have a fitted line given by the dashed line. Points for males are marked with a 0 and the fitted line is the solid line.

the model for the mean function matches the data fairly well, as both the mean and variance functions appear to be constant. The other interesting feature is the poor fit for one athlete with very high RCC. Deleting this case and refitting can tell us about the impact of this point on the fitted equation; doing so results in only minor changes in the estimated coefficients or in $\widehat{\sigma}$. Other separated points can cause very large changes in estimates, and such points are called influential.

Multiple Regression

Many regression problems require consideration of more than one predictor, and it is required to understand how the response y depends simultaneously on the predictors $x_1, x_2, \ldots, x_n$. For example, the dependence of RCC on LBM discussed so far ignores the fact that these data consist of both male and female athletes, and one might reasonably assume that gender differences are important. This will require either fitting separate models for the two populations of males and females, or more generally including gender effects in the mean function. Other problems might require additional predictors; in the athletes data, for example, including height, weight, or some blood chemistry variables might be appropriate.

We begin with p predictors $x_1, \ldots, x_p$, and from these we will build a set of k *terms* $u_0, u_1, \ldots, u_{k-1}$, to get the multiple linear regression mean function

$$\mathrm{E}(y|u_1, \ldots, u_{k-1}) = \beta_0 u_0 + \beta_1 u_1 + \ldots + \beta_{k-1} u_{k-1} \qquad [4]$$

Including terms, which are functions of the predictors, makes this model very general. For example, a model with one predictor x might include the terms $u_0 = 1$ for the intercept, $u_1 = x$, $u_2 = x^2$, and $u_3 = x^3$, so polynomial models are included in the multiple linear regression class. In addition, the u terms can include interactions (e.g., $u = x_1 x_2$), transformations (e.g., $u = \log(x_1)$), and other functions of the predictors. Quantitative variables like gender can be included in a model by defining *factors*, which are sets of indicator variables (often having the values 0 or 1) that correspond to the levels of the factor. For example, the variable *Treatment* with three levels can be included in a model with two indicator variables, the first with the value 1 for units that received treatment T1 and 0 otherwise; the second with the value 1 for units getting treatment T2, and 0 otherwise; T3 is indicated if both indicators are equal to 0. Since gender has only two levels, only one indicator variable is required.

Suppose that Gender has the value 1 for females and 0 for males. Figure 3 shows a fit of the mean function

$$\mathrm{E}(\mathrm{RCC}|\mathrm{LBM},\ \mathrm{Gender}) = \beta_0 + \beta_1\ \mathrm{Gender} + \beta_2\ \mathrm{LBM} + \beta_3\ \mathrm{LBM} \times \mathrm{Gender} \qquad [5]$$

to the athletes data. This is a multiple regression model with two predictors, LBM and Gender, and four terms, an intercept, an interaction, and terms for LBM and Gender. For males, Gender = 0 and eqn [5] becomes

$$\mathrm{E}(\mathrm{RCC}|\mathrm{LBM},\ \mathrm{Gender} = 0) = \beta_0 + \beta_2\ \mathrm{LBM}$$

while for females, Gender = 1 and

$$\mathrm{E}(\mathrm{RCC}|\mathrm{LBM},\ \mathrm{Gender} = 1) = (\beta_0 + \beta_1) + (\beta_2 + \beta_3)\mathrm{LBM}$$

We recognize that this model fits straight lines separately for each gender with intercept and slope β_0 and β_2 for males, and $\beta_0 + \beta_1$ and $\beta_2 + \beta_3$, for females. We see from the fitted least squares lines shown in Figure 3 that within gender the regression have different intercepts (males appear to have higher RCC than females), but the two groups appear to have approximately equal slopes, and those two slopes may well be zero. Thus, by conditioning on group, the relationship between RCC and LBM disappears. Table 2 summarizes the ordinary least squares fit based on model eqn [5]. The fitting method is

Table 2 Multiple linear regression of RCC on LBM and Gender

	Coefficient estimates		
Label	*Estimate*	*Std. error*	*t-value*
Constant	4.85114	0.255403	18.994
Gender	−0.666013	0.372175	−1.790
LBM	0.00234984	0.00339170	0.693
LBM × gender	0.00164645	0.00595363	0.277
R squared		0.466583	
Sigma hat		0.337009	
Number of cases		202	
Degrees of freedom		198	

a direct generalization of the method for simple regression given at eqn [2], except that fit_i is now defined using eqn [5]. We now see that the estimates for LBM and LBM × Gender are very small both in absolute value, and small relative to their standard errors. All this suggests that, given gender, RCC and LBM are independent.

This example illustrates that choice of predictors in a regression problem can be very important. The initial analysis, ignoring gender, suggested that RCC increased with increasing LBM. This spurious dependence appears to be due to gender differences: women have lower values of LBM than men, on the average, and they also appear to have lower values of RCC than do men (at least for elite athletes). The initial analysis reflected gender differences, not a meaningful relationship between the response and the predictor.

Interpreting Parameters

Weisberg (1985) reported the results of a regression to study per capita fuel consumption for the United States as a function of four predictors: *Tax* rate, in cents per gallon, *Dlic*, the fraction of adults with drivers licenses; *Inc*, the per capita income in thousands of dollars, and *Road*, the number of miles of roadway in the state. The fitted linear regression model was:

$$\text{Fuel} = 377 + 35\ \text{Tax} + 13\ \text{Dlic} - 66\ \text{Inc} - 2.4\ \text{Road}$$

Assuming that this mean function is appropriate for these data (a question that should always be considered in trying to understand a regression problem), how are the parameter estimates to be interpreted? For example, the coefficient of −66 for *Inc* suggests that for every $1000 increase in per capita income, fuel consumption will decrease by about 66 gallons per person, assuming that all other predictors could be held fixed at their current values. Similarly, the value of +35 for *Tax* suggests that for every penny increase in fuel tax, consumption goes *up*, contrary to the common sense result that increasing cost through taxes should decrease consumption, assuming all other factors are held fixed. How can this happen?

These data are observational: tax rates are determined by state legislatures in response to many other factors, possibly including the per capita fuel consumption. Thus the observed positive relationship may be due to high consumption causing an increase in taxes, rather than the other way around. There is no way to sort out an issue like this one without actually experimentally changing variables and observing what happens; this is surely not possible in setting tax rates.

As another example, Weisberg (1985) reported on the regression summary of the dependence of accident rate per million vehicle miles on speed limit *Slim*, number of access points *Acpt* and length *Len* of a segment for 39 segments of major Minnesota highways. The fitted model was

$$\text{Rate} = 9.32 - 0.77\ \text{Len} - 0.10\ \text{Slim} + 0.10\ \text{Acpt}$$

We get the sensible result that increasing the number of access points in a segment, while keeping the other two variables fixed, will increase the accident rate by 0.1. The other two coefficients are less obvious. The negative sign for *Slim* suggests that increasing speed limits will lower accident rates (these data predate the original reduction of the maximum speed limit to 55 mph), but once again we cannot tell if higher speeds cause fewer accidents, or if dangerous segments of road encourage the highway department to lower the speed limit; both would give rise to the negative coefficient.

The coefficient for *Len* is also curious; why should accident rate be related to the length of the segment, since the rate is already adjusted for the miles driven? If most accidents occur at isolated dangerous spots that are relatively rare, then increasing the length of a segment by a small amount is unlikely to include another dangerous spot. The longer segment will then have about the same number of accidents, but a lower value for accidents per million vehicle miles. Consequently, the negative association between the rate and the length, adjusted for the other variables, is an artifact of the way the data are collected. It has no intrinsic interest on its own, but it must be included in all regression models to remove the effect of this artifact.

Conclusion

Regression methodology generally seeks to understand the dependence of a response variable on a set of predictors as the predictors are varied. This very general methodology finds application in almost every branch of human inquiry. The approach to regression briefly outlined here is expanded at a relatively low mathematical level in Cook and Weisberg (1999). Fox (1997) provides another entry to the literature on regression, at about the same level. Draper and Smith (1998) requires a modestly higher level of mathematical sophistication.

Almost any of the popular statistical computing package will include programs for fitting the type of models discussed in this article. The larger programs like SAS offer several seemingly different procedures with names like 'proc reg' and 'proc glm' that in reality are just fitting the regression models described here. Newer approaches to regression require extensive use of graphics, and several programs are specifically designed for graphics, for example, the free program Arc that is described in Cook and Weisberg (1999).

Abstract

Regression analysis is the study of how a response variable depends on one or more predictors. In regression graphics we pursue low-dimensional sufficient summary plots. These plots, which do not require a model for their construction, contain all the information on the response that is available from the predictors. They can be used to visualize dependence, to discover unexpected relationships, to guide the choice of a first model, and to check plausible models. This article covers the foundations for sufficient summary plots and how they can be estimated and used in practice. Their relationship to standard model-based graphics such as residual plots is covered as well.

Regression analysis is the study of how a response variable depends on one or more predictors. For example, as a part of an ecological study of New Zealand mussels, we might wish to study the dependence of muscle mass Y (g), the edible portion of a mussel, on the size of the shell as represented by the shell height X_1, shell length X_2, and shell width X_3 (mm). We later use a data set from this study containing observation on 82 mussels.

Graphical displays can be quite useful in regression analysis because they can be used to visualize dependence, to discover unexpected relationships, to guide the choice of a model, and to check and refine plausible models. In this article, we present the basic ideas and methods of regression graphics.

Introduction

The overarching goal of a regression analysis is to understand how the conditional distribution of the response variable Y given a vector of p predictors $\mathbf{X} = (X_j, j = 1,\ldots, p)$ depends on the value assumed by $\mathbf{X}$. While attention is often restricted to the mean function $\mathrm{E}(Y|\mathbf{X})$ and perhaps the variance function $\mathrm{Var}(Y|\mathbf{X})$, in full generality it is the conditional distribution of $Y|\mathbf{X}$ that is of interest. The population of New Zealand mussels can be viewed as consisting of several subpopulations, one for each distinct shell size as represented by the value of $\mathbf{X}$. In the regression we wish to study how the distribution of muscle mass changes as we move between subpopulations.

Linear regression is a restrictive but common form of analysis in which $\mathrm{E}(Y|\mathbf{X})$ is expressed as a linear function of the predictors and the data are used to estimate the unknown coefficients of the predictors (see Linear Hypothesis: Regression (Basics)). For example, we might begin an analysis of the mussel regression by fitting the linear regression model

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \sigma\varepsilon \qquad [1]$$

where ε is an unobservable random error with mean 0 and variance 1, the βs are unknown regression coefficients, and σ is the unknown standard deviation. In this particular model, the distribution of $Y|\mathbf{X}$ depends on $\mathbf{X}$ only through the mean function

$$E(Y|\mathbf{X}) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 \qquad [2]$$

which is linear in $\mathbf{X}$. The variance function is constant $\mathrm{Var}(Y|\mathbf{X}) = \sigma^2$ under the model.

The choice of a model can be problematic, and is often the most difficult part of a regression analysis. Beyond the general notion that linear models may serve as useful approximations, there is little prior information to support model (1) for the mussel regression and data-based modifications may well be required. Graphics can be useful in the choice of a first model. If the mussel regression had only one predictor X_1, a two-dimensional scatter plot of Y vs. X_1 could be used to visualize how the conditional distribution $Y|\mathbf{X}_1$ changes with the value X_1. Similarly, if the regression had only two predictors, say X_1 and X_2, we could use a computer-generated three-dimensional plot of Y vs. (X_1, X_2) to visualize the conditional distributions. But the mussel regression has three predictors, requiring a four-dimensional plot to view the data in full. Four-dimensional plots can not be viewed in their entirety in our three-dimensional world, so we must find indirect low-dimensional methods of viewing regression data when there are more than two predictors.

For instance, a scatterplot matrix of the mussel data is shown in Figure 1. The diagonal cells in the scatterplot matrix serve to name the axes for the individual plots and show the observed range for each variable. The top row contains plots of the response vs. each of the predictors, and the predictors are plotted in the lower left 3×3 array. This scatterplot matrix contains much information: we see that each of the mean functions for the marginal regressions in the top row is curved and that the variance functions are increasing. There are fairly strong linear relationships between the predictors, indicating that collinearity may be an issue. This type of information from low-dimensional plots can be useful but unfortunately may have little to do with the regression of Y on $\mathbf{X}$. The fact that the marginal mean functions $\mathrm{E}(Y|X_j)$, $j = 1, 2, 3$, are curved does not necessarily imply that the full mean function $\mathrm{E}(Y|\mathbf{X})$ is a nonlinear function of $\mathbf{X}$. Similarly, we cannot safely conclude that the variance function $\mathrm{Var}(Y|\mathbf{X})$ is not constant.

Figure 1 Scatterplot matrix for the mussel regression.

Plots of convenience such as the scatterplot matrix of Figure 1 may not portray the regression accurately and can misdirect the analysis. Low-dimensional plots must be constructed and interpreted carefully if we are to avoid such possibilities. In regression graphics we pursue low-dimensional *sufficient summary plots* which contain all the information on Y that is available from $\mathbf{X}$, and which avoid the distortion that can result from simple convenient displays of the data.

Figure 2 shows a summary plot of muscle mass Y vs. the linear combination of the predictors

$$\mathbf{b}^T\mathbf{X} = 0.05X_1 + 0.08X_2 + 0.86X_3 \qquad [3]$$

Figure 2 Summary plot for the mussel regression.

Methods of regression graphics discussed later in this article enable us to infer that this plot is *sufficient* and thus contains all the information on muscle mass Y that is available from the three predictors in $\mathbf{X}$, namely shell height, length, and width. Because the plot is inferred to be sufficient and because no model was used in its construction, we can use it to guide the remaining analysis including the choice of a first model. We conclude from the plot that the mean function is curved and that the variance function is very likely not constant. Both conclusions contradict model (1).

Sufficient Summary Plots

Dimension reduction is a leitmotif of statistics. For instance, starting with a sample $z_1,\ldots, z_n$ from a univariate normal population with mean, μ and variance 1, we know that the sample mean $\bar{z}$ is sufficient for μ (see Statistical Sufficiency). This means that we can replace the original n-dimensional sample with the one-dimensional mean $\bar{z}$ without loss of information on μ.

In the same spirit, dimension reduction without loss of information is a dominant theme of regression graphics. The goal of a regression study is to infer about the conditional distribution of the response Y given the $p \times 1$ vector of predictors $\mathbf{X}$. A central goal of regression graphics is to reduce the dimension of $\mathbf{X}$ without loss of information on the conditional distribution of $Y|\mathbf{X}$ and without requiring a model. We call this sufficient dimension reduction, borrowing terminology from classical statistics. Sufficient dimension reduction leads naturally to sufficient summary plots which contain all of the information on the regression that is available from the sample.

In regression graphics we search for the smallest number $d \leq p$ of linear combinations of the predictors, say $\mathbf{b}_1^T\mathbf{X}, \ldots, \mathbf{b}_d^T\mathbf{X}$, that contain all the information about Y that is available from $\mathbf{X}$. To formalize this idea, we re-express it in the form of a conditional independence statement

$$Y \perp\!\!\!\perp \mathbf{X} | \mathbf{B}^T\mathbf{X} \qquad [4]$$

Here columns of the $p \times d$ matrix $\mathbf{B}$ are the vectors $\mathbf{b}_1,\ldots, \mathbf{b}_d$ so that $\mathbf{B}^T\mathbf{X}$ is the $d \times 1$ vector of linear combinations $\mathbf{b}_1^T\mathbf{X}, \ldots, \mathbf{b}_d^T\mathbf{X}$. The notation '$\perp\!\!\!\perp$' means independence. The statement is, thus, that Y is independent of $\mathbf{X}$ given any values for the d linear combinations $\mathbf{B}^T\mathbf{X} = (\mathbf{b}_1^T\mathbf{X}, \ldots, \mathbf{b}_d^T\mathbf{X})^T$. The value of d is called the structural dimension of the regression of Y on $\mathbf{X}$, and we refer to a regression as having kD structure for $k = 0, 1,\ldots, p$. We can always find a value of d and a corresponding matrix $\mathbf{B}$ so that Egn(4) is true. For example, (4) is always true when $d = p$ and $\mathbf{B} = \mathbf{I}$.

If a regression has 0D structure, then $Y \perp\!\!\!\perp \mathbf{X}$, and the predictors contain no information about the response. In such cases, a simple histogram or other graphical representation of the marginal distribution of Y is a sufficient summary plot. If $d = 1$ then all the information about Y that is available from $\mathbf{X}$ is contained in a single linear combination $\mathbf{b}_1^T\mathbf{X}$, and a plot of Y vs. $\mathbf{b}_1^T\mathbf{X}$ is a sufficient summary plot for the regression. Under 2D structure all the information about Y that is available from $\mathbf{X}$ is contained in two linear combinations $\mathbf{b}_1^T\mathbf{X}, \mathbf{b}_2^T\mathbf{X}$, and

a three-dimensional plot of Y vs $\mathbf{b}_1^T\mathbf{X}, \mathbf{b}_2^T\mathbf{X}$ is a sufficient summary plot for the regression.

Each of the following regression models is an example of a regression with 1D structure.

$$Y = b_0 + \mathbf{b}^T\mathbf{X} + \sigma\varepsilon \quad [5]$$

$$Y^{(\lambda)} = b_0 + \mathbf{b}^T\mathbf{X} + \sigma\varepsilon \quad [6]$$

$$Y = f(\mathbf{b}^T\mathbf{X}) + \sigma\varepsilon \quad [7]$$

$$Y = f(\mathbf{b}^T\mathbf{X}) + \sigma(\mathbf{b}^T\mathbf{X})\varepsilon \quad [8]$$

Model (5) is the linear regression model. In model (6) we have a linear regression model after some response transformation represented by the unknown parameter λ. The mean function in model (7) is $E(Y|\mathbf{X}) = f(\mathbf{b}^T\mathbf{X})$, where f may be unknown or known, but it depends on only one linear combination of the predictors and thus the regression still has 1D structure. Similarly, in model (8) both the mean and standard deviation functions may depend on $\mathbf{b}^T\mathbf{X}$. Generalized linear models with corresponding link functions also have 1D structure. The class of regression models with 1D structure is quite large and covers many models used in practice. A regression model with 2D structure can be considerably more complex that a regression with 1D structure. The model

$$Y = f(\mathbf{b}_1^T\mathbf{X}, \mathbf{b}_2^T\mathbf{X}) + \sigma(\mathbf{b}_1^T\mathbf{X}, \mathbf{b}_2^T\mathbf{X})\varepsilon$$

is one example of a regression with 2D structure.

The structural dimension d of a regression and the corresponding linear combinations $\mathbf{B}^T\mathbf{X}$ will generally be unknown. In the next section we discuss methods for estimating these quantities, leading to estimated sufficient summary plots.

Estimating Sufficient Summary Plots

There are several methods for estimating sufficient summary plots or properties thereof. While there are no restrictive constraints placed on the foundations of regression graphics as represented by Eqn. [4], some constraints are necessary for estimation. The most notable is that there should be no strong nonlinear relations among the predictors. This requirement constrains the marginal distribution of $\mathbf{X}$ and not the conditional distribution of $Y|\mathbf{X}$ as is usual when modeling in practice. It is part of the cost of insuring that certain low-dimensional plots contain useful information on the regression. There are several methods for insuring that this requirement holds in practice, including the possibility of using power transformations of the predictors to remove extreme nonlinearities.

Returning to the scatterplot matrix in Figure 1, we see that the mean functions in the predictor plots are all strongly linear, and thus we can proceed to infer about properties a sufficient summary plot. A first inference is available from the *inverse response plots* of X_j vs. Y in the last column of the scatterplot matrix. Since all of these plots have the same shape we infer that $d = 1$ and thus that there is a two-dimensional sufficient summary plot. The justification for this conclusion is based on the vector of inverse mean functions $E(\mathbf{X}|Y)$. If all inverse mean functions are linear related so that for some function $m(Y)$ of the response $E(X_j|Y) = E(X_j) + \alpha_j m(Y)$, $j = 1,\ldots, p$, then 1D structure is indicated. Next, if $d = 1$ as we have just inferred then there is a $p \times 1$ vector $\mathbf{b}$ such that (a) $Y \perp\!\!\!\perp \mathbf{X}|\mathbf{b}^T\mathbf{X}$ and (b) a plot of Y vs. $\mathbf{b}^T\mathbf{X}$ is a sufficient summary of the regression.

The next issue in our discussion of the mussel data is how to estimate $\mathbf{b}$. If there are no strong nonlinear relations among the predictors then $\mathbf{b}$ can be estimated as the coefficient vector of $\mathbf{X}$ from the ordinary least squares regression of Y on $\mathbf{X}$. And the estimated sufficient summary plot can be taken as a plot of Y vs. the fitted value $\hat{Y}$ from this same regression. This is how the summary plot of Figure 2 was produced. No model is being assumed in this use of ordinary least squares. Indeed, we saw previously that the multiple linear regression model (1) is not sustained by the data. Nevertheless, the estimated coefficient vector $(\widehat{\beta}_1, \widehat{\beta}_2, \widehat{\beta}_3)^T$ still provides a consistent estimate of $\mathbf{b}$. Estimation methods other than least squares can be used as well, provided the objective function is convex.

There are several more comprehensive methods for inferring about sufficient summary plots. All are based on transforming the original vector $\mathbf{X}$ of p predictors to p estimated linear combinations

$$\mathbf{X} = \begin{pmatrix} X_1 \\ X_2 \\ \vdots \\ X_p \end{pmatrix} \rightarrow \mathbf{Z} = \begin{pmatrix} \widehat{\mathbf{b}}_1^T\mathbf{X} \\ \widehat{\mathbf{b}}_2^T\mathbf{X} \\ \vdots \\ \widehat{\mathbf{b}}_p^T\mathbf{X} \end{pmatrix}$$

The p estimated linear combinations $\widehat{\mathbf{b}}_j^T\mathbf{X}$ are ordered on the likelihood that they will be needed in a sufficient summary plot. If it is inferred that $d = 0$ then none of the linear combinations is needed. If it is inferred that $d = 1$ then only the first is needed and a plot of Y vs. $\widehat{\mathbf{b}}_1^T\mathbf{X}$ is the estimated summary plot. Similarly, if the structural dimension is inferred to be $d = 2$ then only the first two estimated linear combinations are needed and a three-dimensional plot of Y vs. $(\widehat{\mathbf{b}}_1^T\mathbf{X}, \widehat{\mathbf{b}}_2^T\mathbf{X})$ is the estimated summary plot.

There are three primary numerical methods for producing the vector $\mathbf{Z}$ of linearly transformed predictors, each with its own advantages and disadvantages

a. Sliced Inverse Regression (SIR)
b. Sliced Average Variance Estimation (SAVE)
c. Principal Hessian Directions (pHd)

SIR and SAVE use the column of inverse response plots in a scatterplot matrix of the predictors and the response, as discussed previously in connection the mussel data. They measure the shape of the inverse response plots by first replacing the response Y with a discrete version $\tilde{Y}$ constructed by partitioning the range of Y into K *slices*. SIR then gauges the shapes of the inverse mean functions $E(\mathbf{X}|\tilde{Y})$, while SAVE gauges the shapes of the inverse functions $E(\mathbf{X}|\tilde{Y})$ and the inverse variance functions $\mathrm{Var}(\mathbf{X}|\tilde{Y})$ simultaneously. The number of slices is a tuning parameter in both approaches. pHd is based on third moments between the response and the predictors, and does not have a tuning parameter. Each method comes with an inference procedure for the structural dimension d of the regression. In particular, beginning with $\mathbf{Z}$ predictors, graphical regression is

Figure 3 Estimated sufficient summary plot from SAVE for the bank note data.

Figure 4 Scatterplot of residuals versus fitted values from the ordinary least squares fit of model.

a method for visually estimating the structural dimension of a regression and the corresponding summary plot.

SIR is good at estimating sufficient summary plots with linear trends, but it does not generally work well for finding plots with curvature and little linear trend. pHd works best for finding quadratic trends. SAVE is the most comprehensive, but may miss information when it is concentrated in linear trends where SIR works well.

We use a data set on 200 Swiss bank notes for illustration. The response is binary with $Y = 1$ indicating a counterfeit note and $Y = 0$ indicating a genuine note. The methods of regression graphics discussed previously apply equally to regressions with continuous and binary responses. There are six predictors, each giving a different aspect of the size of a note: $X_1 =$ length of bottom edge, $X_2 =$ diagonal length, $X_3 =$ left edge length, $X_4 =$ length at center, $X_5 =$ right edge length, and $X_6 =$ top edge length.

Application of SAVE to the bank note data indicated 2D structure. Shown in Figure 3 is a binary response plot of the first two linear combinations $(\widehat{\mathbf{b}}_1^T\mathbf{X}, \widehat{\mathbf{b}}_2^T\mathbf{X})$. We infer that this plot contains all the information about a note's authenticity that is available from the six predictors. The summary plot shows an outlying genuine note, good separation between the genuine and counterfeit notes, and a bimodal distribution within the counterfeit notes. The outlying genuine note could be a mislabeled counterfeit note, and the bimodal distribution within the counterfeit notes might reflect two different production processes.

Special Purpose Graphics

In addition to sufficient summary plots, there are a variety of special purpose graphics that can be used to address specific issues. These visualization methods mostly center on assessing or improving a target model.

Perhaps the most common graphical methods of model assessment are based on searching for dependence between residuals from the fitted model and the predictors. The various methods for estimating sufficient summary plots can be used to detect such dependence by simply using residuals in place of the response. In this setting the model is sustained when no information is found to contradict 0D structure.

A plot of residuals vs. fitted values from the ordinary least squares fit of model (1) is shown in Figure 4. The horizontal line intersecting zero on the vertical axis was added as a visual reference. If the model was correct, this plot should leave the impression that the residuals are independent of the fitted values. Because the residuals and fitted values in the plot are clearly dependent, we have information to contradict 0D structure and the model is called into question.

CERES plots, including the class of partial residual plots can be used to study the need for predictor transformations in a multiple regression model such as model (1). Similar graphical methods are available for studying the need for response transformations. Net-effect plots can be used to study the contribution of a selected predictor to the regression. Versions are available for both model-based and model-free regression studies. Marginal model plots can be used to assess model adequacy.

Further Reading

The approach to regression graphics based on sufficient summary plots and many special purpose graphics were discussed at a relatively low mathematical level by Cook and Weisberg (1999). A more advanced treatment that requires knowledge of linear models and linear algebra was given by

Cook (1998a). Sliced inverse regression and the method of principal Hessian directions were proposed by Li (1991, 1992). Sliced average variance estimation was proposed by Cook and Weisberg (1991). Extensions of these methods were studied by Cook (1998b), Ferré (1998), Filliben and Li (1997), Hsing and Carroll (1992), Schott (1994), Velilla (1998), and Zhu and Fang (1996). Graphical regression was proposed by Cook (1998a). The mussel data were taken from Camden (1989). The bank note data were taken from Flury and Riedwyl (1988); the analysis follows Cook and Lee (1999) who studied regressions with a binary response.

Linear Mixed Models

Abstract

The focus of this article is on a class of regression models that are widely used for the analysis of cluster-correlated data. Linear mixed models are a natural extension of classical linear regression models that allow for the incorporation of random effects to account for the correlation among repeated measures on the same individual or cluster. Linear mixed models are used extensively for the analysis of longitudinal data as well as cluster-correlated data arising from other types of study designs. This article describes a general linear mixed model for clustered continuous data, outlining the model development and its underlying assumptions. Many of the conceptual ideas that are fundamental to understanding mixed models are reinforced using graphical representations of the linear mixed model equations. Finally, an example, based on data from a longitudinal study of growth in body fat in girls before and after menarche, is used to illustrate the application of linear mixed models.

This article discusses a class of regression models that are widely used for the analysis of cluster-correlated data. Linear mixed models are used extensively in settings where multiple correlated measurements are made on the sampling unit of interest (e.g., repeated measurements on a subject over time or observations of subjects nested within larger units, such as employees within workplaces, patients within medical clinics). In the social and behavioral sciences, these models are routinely applied to data from longitudinal studies and to cluster-correlated data arising from other types of study designs (e.g., measurements of children who are nested within different classrooms). This article presents the essential features of a general linear mixed model for longitudinal and cluster-correlated Gaussian data. In Section Longitudinal and Clustered Data we describe a number of study designs that give rise to data with outcomes measured repeatedly on each subject or cluster, highlighting some of the potential complexities for analysis. In Section Linear Mixed Models the main features of the linear mixed model, and its underlying assumptions are discussed. Key ideas are reinforced using graphical representations of the mixed model equations. In Section Example: MIT Growth and Development Study the model and methods are illustrated through an example using data from the MIT Growth and Development Study, a longitudinal study of growth in body fat in girls before and after menarche.

Introduction

Linear mixed models can be considered an extension of classical linear regression models that allow for the incorporation of random effects to account for the correlation among repeated measures on the same subject or cluster. Mixed models are widely used in the analysis of longitudinal and cluster-correlated data. Recall that in a longitudinal study, measurements of the outcome on the same individuals are taken repeatedly over time. A distinctive feature of longitudinal data is that they are *clustered*. In a longitudinal study the cluster is composed of repeated measurements obtained from a single individual. There are many study designs that are not longitudinal but give rise to data with outcomes measured repeatedly on each *cluster*. For example, clustered data commonly arise when intact groups are randomized to interventions or when naturally occurring groups in the population are randomly sampled. An example of the former is group-randomized trials. In a group-randomized trial, also known as a cluster-randomized trial, groups of individuals, rather than each individual alone, are randomized to different treatments or interventions. Data on the outcome of interest are obtained on all individuals within a group. Alternatively, clustered data can arise from random sampling of naturally occurring groups in the population. Families, households, hospital wards, medical practices, neighborhoods, and schools are all instances of naturally occurring clusters in the population that might be the primary sampling units in a study. Also, there are certain study designs that are both clustered and longitudinal, for example, multicenter longitudinal clinical trials where subjects, nested within clinics, are measured repeatedly over time.

In all these examples where clustered data arise, we might reasonably expect that measurements on units within a cluster are more similar than measurements on units in different clusters. That is, observations between distinct clusters are independent of one another, but observations within a cluster are emphatically not. The degree of clustering can be expressed in terms of correlation among the measurements on units within the same cluster. Importantly, this correlation invalidates the crucial assumption of independence that is the cornerstone of so many standard statistical techniques. Instead, statistical models for clustered data must explicitly account for the intracluster correlation. One popular method of accounting for the correlation is via the incorporation of random subject or cluster effects into the model. Specifically, the linear mixed model is an extension of the classical linear regression model for cross-sectional data in which random effects are introduced in the model. The random effects can be thought of as underlying (or latent) individual or cluster effects that account for the correlation among repeated measures on the same individual or cluster. The resulting regression model is a 'mixed model,' in the sense that it combines the usual fixed effects or population regression parameters with random effects (i.e., models that contain both fixed and random effects are called *mixed models*).

Mixed models for continuous normal outcomes have been extensively developed since the seminal papers by Harville (1977) and Laird and Ware (1982). The incorporation of random effects offers several benefits when modeling clustered data. First, it provides great flexibility in modeling the correlation in *unbalanced* designs, for example, in longitudinal studies where measurements are made at arbitrary, irregularly spaced intervals. Second, random effects can be used to estimate or predict subject-specific or cluster-specific effects. Finally, it provides an optimal way to combine the information from two distinct sources of variability in the outcome and covariates: within-subject (or within-cluster) and between-subject (or between-cluster) variability. In this article we review the main features of linear mixed models. To fix ideas, we first introduce a simple special case of the linear mixed model with a single random effect. Later, we describe a general linear mixed model for correlated data with multiple random effects and discuss its underlying assumptions. The model and methods are illustrated through an example from a longitudinal growth study. Before discussing linear mixed models, we highlight a number of study designs where clustered data commonly arise.

Longitudinal and Clustered Data

In this section we briefly discuss various types of study designs that give rise to data with outcomes measured repeatedly on each subject and highlight some of the potential complexities for analysis. Longitudinal study designs are widely used in the social and behavioral sciences to measure intraindividual change over time. In longitudinal studies subjects are measured repeatedly throughout the duration of the study, thereby permitting the direct assessment of changes in the outcome variable over time. Longitudinal studies are popular because many factors, which can confound age effects estimated in cross-sectional studies, are automatically controlled for by measuring change within-subjects. The main goal of a longitudinal study is to characterize within-individual changes in the outcome over time and to determine whether they are related to selected covariates. Often we wish to study change as a function of an intervention (e.g., drug treatment), an event (e.g., onset of puberty), or individual characteristics (e.g., gender, exposures). Typically, although not always, longitudinal study designs call for a fixed number of repeated measurements to be made on all study participants at a set of common time points. However, it is an almost inescapable feature of longitudinal studies in the social and behavioral sciences, especially those where the repeated measurements extend over a relatively long duration, that some individuals will miss their scheduled visit or date of observation. In some studies this may necessitate that observations be made some time before or after the scheduled time. Consequently the sequence of observation times is no longer common to all individuals in the study due to mistimed and/or missing measurements. In that case we refer to the data as being 'unbalanced' over time, that is, the repeated measurements are not obtained at a common set of occasions. As noted earlier, a distinctive feature of longitudinal data is that they are clustered. In longitudinal studies the clusters are composed of the repeated measurements obtained from a single individual at different occasions. That is, subjects can be thought of as the basic sampling unit, and the outcome is measured repeatedly on subjects.

There are numerous study designs that produce clustered data. Data of this kind frequently arise in the social and behavioral sciences because individuals can be grouped in many different ways. For example, in studies of educational performance, assessments are often obtained from children who are nested within different classrooms. Such data are clustered, with classroom considered to be the sampling unit and the repeated observations are the children within the classroom. Data from studies of nuclear families are also clustered, with observations on the mother, father, and children nested within families. Other common examples of naturally occurring clusters in the population are households, neighborhoods, districts, workplaces, departments, clinics, and litters. In many (although not all) of these study designs that produce clustered data the main interest is in the effects of covariates that vary between-clusters (i.e., between-cluster effects); this is in contrast to longitudinal designs, where interest is in within-subject (within-cluster) effects. Also, we note that clustering can occur at numerous levels in a data structure. For example, observations may be obtained on patients nested within clinics, which in turn are nested within different geographical regions of the country. Another example is when observations are obtained on children nested within classrooms, nested within schools. Regardless of the exact nature of the clustering, its consequence for analysis is the same: measurements on units within a cluster tend to be more similar (i.e., positively correlated) than the measurements on units in different clusters. In general, the degree of clustering can be expressed in terms of correlation among the observations on units within a cluster. To make valid inferences, statistical models for clustered data must appropriately account for this intracluster correlation. The magnitude of the positive intracluster correlation has important implications for precision. In longitudinal studies where the focus is on within-subject effects, the positive correlation among repeated measures allows for the estimation of the effects of change over time with greater precision (smaller standard error). In contrast, the effects of covariates that vary between-clusters are estimated with less precision (larger standard error) due to the positive intracluster correlation. For ease of exposition, in the remainder of this article we focus on applications of linear mixed models to longitudinal data, but it should be apparent how the models can also be applied to cluster-correlated data more broadly defined. Before turning to model development, we introduce an example that will be used later to illustrate an application of linear mixed models.

The MIT Growth and Development Study (Bandini et al., 2002; Phillips et al., 2003; Naumova et al., 2001; Fitzmaurice et al., 2011) was an observational study designed to characterize how measures of body fat change in girls before and after the onset of menarche. While it is accepted that body fat increases about the time of menarche, of interest was whether the increase persisted up to 4 years then. Premenarche, non-obese girls were selected in the study and measured annually until 4 years after menarche, or the end of follow-up. At each annual assessment, a measure of percent body fat was obtained based on bioelectric impedance analysis, a widely used method

Figure 1 Scatter plot of percent body fat against time, relative to age of menarche (in years), with *lowess* smoothed curve.

for estimating body composition. The time of menarche was also recorded for each participant. While the design is almost balanced with respect to calendar time (with the exception of the final measurement, the design is balanced), what is of greater relevance to the scientific question of interest is the time relative to menarche. That is, for the purpose of analysis, the timing of measurement must be rescaled so that a value of zero corresponds to menarche, a positive value indicates time after menarche, and a negative value denotes time before menarche. Since menarche is a random event, differing for each girl, the resulting sample design is quite unbalanced. Although most girls had four measurements after menarche, the number of measures taken before was not fixed by design. Figure 1 illustrates all of the data points plotted against time relative to menarche. Note the cluster of measures at 4 years post-menarche is by design, but the other measures are scattered at random times. The trend in the mean response over time can be assessed using a *lowess* smoothed curve. Lowess is a nonparametric, robust regression method that traces the salient features of the mean response as a function of time while making only minimal assumptions about the form of the relationship. The lowess curve in Figure 1 reveals that the mean response remains relatively flat during the premenarcheal period and then rises sharply during the postmenarcheal period. We will return to this example in Section Example: MIT Growth and Development Study.

Linear Mixed Models

We first introduce some notation that will be adopted for the remainder of the article. Laird and Ware (1982) established a notation that is very commonly used in longitudinal studies, where Y_{ij} denotes the outcome measurement taken on the ith subject at the jth occasion. Notice that in balanced designs, we could choose to let j index time itself (e.g., $j = 1$ denotes time 1, $j = 2$ denotes time 2, etc.), but this is not workable in unbalanced designs where different individuals are measured at different times. Hence, we let j index measurement number rather than time or occasion; we use the terms time or occasion somewhat interchangeably to denote the specification of measurements in the design. Thus j varies from 1 to n_i, where n_i is the total number of observations obtained on the ith subject. Adopting this notation means that it will be necessary to explicitly introduce time of measurement in the models for the mean response and the covariance among repeated measurements. However this provides us with a flexible notation for handling missing data and unbalanced designs.

Before we discuss the general linear mixed model for Y_{ij}, we first consider the simplest possible case of a linear mixed model, a model with randomly varying subject effect or random intercept:

$$\begin{aligned} Y_{ij} &= \beta_0 + \beta_1 X_{ij1} + \beta_2 X_{ij2} + \cdots + \beta_p X_{ijp} + b_{0i} + \varepsilon_{ij} \\ &= (\beta_0 + b_{0i}) + \beta_1 X_{ij1} + \beta_2 X_{ij2} + \cdots + \beta_p X_{ijp} + \varepsilon_{ij} \end{aligned} \quad [1]$$

where the βs are the fixed regression coefficients, the X_{ij}s are vectors containing the p covariates for the ith subject at the jth occasion, b_{0i} is the random subject effect (or random intercept), and ε_{ij} is a random error term. In this model b_{0i} and ε_{ij} are assumed to be mutually independent, with mean zero, and with variances, $\mathrm{Var}(b_{0i}) = \sigma_b^2$ and $\mathrm{Var}(\varepsilon_{ij}) = \sigma_\varepsilon^2$. Because the mean of the random subject effect is assumed to be zero, b_{0i} represents the deviation of the ith individual's intercept $(\beta_0 + b_{0i})$ from the population intercept, β_0. The assumption of zero mean for the random effect also implies that an ordinary linear regression model for the mean of Y_{ij} holds:

$$E(Y_{ij}|X_{ij}) = \beta_0 + \beta_1 X_{ij1} + \beta_2 X_{ij2} + \cdots + \beta_p X_{ijp} \quad [2]$$

when averaged over the distribution of the random effect. That is, the linear mixed model for Y_{ij} in eqn [1] also implies a linear regression model for the marginal mean (averaging over the random effect) of Y_{ij} in eqn [2]. Here the βs model the so-called *fixed effects*, that is, the time effects, as well as the effects of interventions or covariates, and their interactions.

For this simple case of a linear mixed model the fundamental ideas can be best understood by considering the graphical representation of the model equations for the simple case where a subject's expected response varies linearly over time. Figure 2 displays how the marginal mean response over time in the population changes linearly with time (denoted by the solid line), but also indicates how the subject-specific mean response for two individuals (denoted by the broken lines), say subjects A and B, deviate from the population trend. In Figure 2, individual A responds 'higher' than the population average and thus has a positive b_{0i}. In contrast, individual B responds 'lower' than the population average and has a negative b_{0i}. The inclusion of the errors, ε_{ij}, allows the response at any occasion to vary randomly above and below the subject-specific trajectories.

In general, the random effect, b_{0i} can be interpreted in several ways. As described above, it provides a measure of how the ith subject deviates from the marginal mean. Alternatively, we can think of b_{0i} as representing the ith subject's underlying

Figure 2 Graphical representation of the marginal (averaged over subjects) and subject-specific mean response over time, plus errors.

(or latent) level of response that persists over time and influences all repeated measurements on that subject, thereby providing a device for introducing correlation among the repeated measures. The latter follows from the fact that any two observations on the ith subject, say Y_{ij} and Y_{ik}, will be correlated because they share the same random effect, b_{0i}.

Next, consider the marginal covariance (variances and correlations) among the repeated measurements. For the simple model with random intercepts, the marginal variance at each occasion is simply $\mathrm{Var}(Y_{ij}) = \sigma_b^2 + \sigma_\varepsilon^2$. This expression implies that $\mathrm{Var}(Y_{ij})$ is constant over time. The correlation between any pair of repeated measurements, say Y_{ij} and Y_{ik}, is

$$\mathrm{Corr}\left(Y_{ij}, Y_{ik}\right) = \frac{\sigma_b^2}{\sigma_b^2 + \sigma_\varepsilon^2}$$

This implies that all pairwise correlations are the same, regardless of the time separation between any pair of repeated measurements. One justification for this correlation structure is it assumes that conditional on a specific subject, repeated observations taken on that subject are independent. This may be reasonable in many cluster-correlated data settings. In these settings, one can consider the within-cluster subjects to be exchangeable. That is, all subjects have the same level of variability and the correlation for all pairs of subjects is the same. For example, this assumption is reasonable when the data are clustered, with classroom considered to be the sampling unit and the repeated observations are the children within the classroom. However, it is rarely useful in longitudinal studies because the assumption that variances and correlations are constant throughout the period of the study is generally unrealistic. Some degree of heterogeneity of the variability over time is not uncommon in longitudinal studies. In addition, ordinarily the pairwise correlations among repeated measures tend to decrease with increasing time separation.

More useful structures for the variances and correlations among the repeated measurements are obtained by enriching the model with multiple random effects. One popular approach is to assume each individual has her own subject-specific intercept and slope. If we assume a linear trend to model change over time, the corresponding mixed model is given by:

$$\begin{aligned} Y_{ij} &= \beta_0 + \beta_1 t_{ij} + b_{0i} + b_{1i} t_{ij} + \varepsilon_{ij} \\ &= (\beta_0 + b_{0i}) + (\beta_1 + b_{1i}) t_{ij} + \varepsilon_{ij} \end{aligned} \qquad [3]$$

where t_{ij} denotes the time of the jth measurement on the ith subject, the random effect, b_{0i} represents the deviation of the ith subject's intercept from the population intercept, β_0, and the random effect, b_{1i} represents the deviation of the ith subject's slope from the population slope, β_1. A graphical representation of the model equations is displayed in Figure 3. Figure 3 illustrates how the marginal mean response in the population changes linearly with time (denoted by the solid line), but also indicates how the subject-specific mean responses (denoted by the broken lines) for two specific individuals, say subjects A and B, deviate from the population trend. In this simple illustration, individual A has a 'higher' baseline level of response (when $t_{ij} = 0$) than the population average and thus has a positive b_{0i}. In contrast, individual B has a 'lower' baseline level of response than the population average and thus has a negative b_{0i}. In addition individual A has a steeper rate of increase over time than the population average and thus has a positive b_{1i}. Individual B has a less steep rate of increase over time than the population average and thus has a negative b_{1i}.

The inclusion of both randomly varying intercepts and slopes has important ramifications for the variances and correlations among the repeated measurements. The variance of the response at the jth occasion is

$$\mathrm{Var}\left(Y_{ij}\right) = \mathrm{Var}(b_{0i}) + 2t_{ij}\mathrm{Cov}(b_{0i}, b_{1i}) + t_{ij}^2\mathrm{Var}(b_{1i}) + \mathrm{Var}\left(\varepsilon_{ij}\right)$$

Figure 3 Graphical representation of the marginal (averaged over subjects) and subject-specific mean response over time, plus errors.

Similarly, it can be shown that the covariance between any pair of repeated measurements, say, Y_{ij} and Y_{ik} obtained at times t_{ij} and t_{ik}, respectively, is

$$\mathrm{Cov}(Y_{ij}, Y_{ik}) = \mathrm{Var}(b_{0i}) + (t_{ij} + t_{ik})\mathrm{Cov}(b_{0i}, b_{1i}) + t_{ij}t_{ik}\mathrm{Var}(b_{1i})$$

By incorporating both randomly varying intercepts and slopes, the variances and correlations are functions of time, t_{ij}. Specifically, the variance can increase or decrease over time as a quadratic function of the times of measurement. Similarly the magnitude of the covariance (and correlation) between a pair of responses, say Y_{ij} and Y_{ik}, depends on the time separation between them (t_{ij} and t_{ik}).

In the simple illustration above there are randomly varying intercepts and slopes. However, the linear mixed effects model can be generalized to incorporate additional randomly varying regression coefficients and to allow the means of the random effects to depend on covariates (e.g., interventions, gender). To handle this additional complexity, a general linear mixed model for Y_{ij} can be written as

$$Y_{ij} = \beta_0 + \beta_1 X_{ij1} + \beta_2 X_{ij2} + \cdots + \beta_p X_{ijp} + b_{0i} + b_{1i} Z_{ij1} + b_{2i} Z_{ij2} + \cdots + b_{qi} Z_{ijq} + \varepsilon_{ij} \quad [4]$$

where the βs are the fixed regression coefficients, the X_{ij}s are the p covariates for the ith subject at the jth occasion, the b_is are the q random effects for the ith subject, the Z_{ij}s are the corresponding covariates (or design) for the random effects, and ε_{ij} is a random error term. Several important assumptions are commonly made for the linear mixed model. First, it is assumed that the collection of b_is has a multivariate normal distribution, with zero mean, and unstructured covariance matrix (i.e., arbitrary variances and pairwise correlations among the random effects). It is standard to assume the random effects have a normal distribution, although, in principle, other distributional assumptions could be made depending on the application (see, for example, Lee and Nelder, 1996). It is also assumed that the errors, ε_{ij} have a normal distribution with zero mean and that ε_{ij} and the b_is are mutually independent of each other. As discussed above, the assumption of zero means for the random effects implies that a linear regression model for the marginal mean (averaging over the random effects) of Y_{ij} holds:

$$E(Y_{ij}|X_{ij}) = \beta_0 + \beta_1 X_{ij1} + \beta_2 X_{ij2} + \cdots + \beta_p X_{ijp} \quad [5]$$

For the remainder, we focus on the specification of the random error terms, since modeling the mean response is not fundamentally different from choosing an ordinary linear regression model for the mean response over time. A consequence of the zero mean assumption for the random effects is that ordinarily the Z_{ij}s must be a subset of the X_{ij}s. The reason for this is not immediately obvious, but stems from the fact that $b_{0i} + b_{1i}Z_{ij1} + b_{2i}Z_{ij2} + \cdots + b_{qi}Z_{ijq}$ can then be usefully interpreted as an 'error' defined with respect to the marginal mean curve defined by eqn [5].

In principle, the random effects part of the model can be made as complex as desired through the inclusion of additional Z_{ij}s and random effects to the model. For example, Donnelly et al. (1995) discuss a model for longitudinal growth in lung function where the subject-specific trajectories depend not only on age of measurement, but also on height at the jth measurement. However, in practice, some care must be exercised in specifying random effects in the model because the variance components parameters may be poorly estimated if the model is too large. An alternative approach is to keep the random effects part of the model simple (e.g., random intercepts) but incorporate serial correlation structure in the errors, ε_{ij} (e.g., autoregressive correlated errors); see, for example, Diggle (1988) and Diggle et al. (2002). In general, it is not possible to enrich both the complexity of the random effects and the correlation structure of the errors as this can lead to identifiability problems due to an overparameterized covariance matrix for the repeated measurements. For example, in many longitudinal studies there may be insufficient information in the data at hand to support separate estimation of randomly varying intercepts and slopes in addition to a complex serial correlation structure (e.g., autoregressive) for the within-subject errors.

Finally, we note that in many applications where linear mixed models are applied, inference is focused on the βs, the fixed effects. However, in some applications, we may want to estimate the subject-specific effects. For example, in studies of growth it may be of interest to obtain subject-specific growth trajectories. In other types of longitudinal studies, it may be of interest to identify those individuals who showed the greatest increase or decrease in the outcome over time. Because the linear mixed model explicitly distinguishes between fixed and random effects, it is possible to estimate (or predict) the subject-specific effects, the b_is, or the subject-specific response trajectories $(\beta_0 + \beta_1 X_{ij1} + \beta_2 X_{ij2} + \cdots + \beta_p X_{ijp} + b_{0i} + b_{1i}Z_{ij1} + b_{2i}Z_{ij2} + \cdots + b_{qi}Z_{ijq})$. In general, the statistical problem of predicting a random variable can be shown to be that of predicting its conditional mean, given the available data. Thus the best predictor of the b_is is their conditional mean, given the collection of repeated measures Y_{ij} (for $j = 1,\ldots,n_i$) on the ith subject. Under the assumptions of the linear mixed model, this is known as the 'best linear unbiased predictor' (BLUP). We note that the BLUP estimators of the b_is are often called 'shrinkage' estimators because they tend to 'shrink' the predictions of the b_is toward zero (the population mean of the random effects). The amount of shrinkage depends on the relative magnitudes of the within-subject and between-subject sources of variability. In general, when the within-subject variability is relatively larger than the between-subject variability there can be discernible shrinkage. Conversely, when the between-subject variability is relatively larger than the within-subject variability, there is far less shrinkage. In addition, the amount of shrinkage depends also on n_i, the number of observations on the ith subject. In general, there is more shrinkage when n_i is small. Intuitively, this is quite sensible since less weight should be given to the ith subject's observations when fewer are available.

Example: MIT Growth and Development Study

To highlight some of the main ideas discussed so far, we consider a longitudinal analysis of the data on percent body fat from the MIT Growth and Development Study. Recall from Figure 1 that the lowess curve reveals that the mean response remains relatively flat during the premenarcheal period and

then rises sharply during the postmenarcheal period. In the following analysis we consider the hypothesis that percent body fat increases linearly with age, but with different slopes before and after menarche. A linear mixed model approach was taken to fit a linear spline, with a knot at time zero (here denoting menarche) to the measurements of percent body fat over time. Recall that the main question of interest was whether the slope on time changes after menarche, hence using a linear spline makes it easy to address this question. Specifically, we assumed that each girl has a piecewise linear spline growth curve with a knot at the time of menarche. That is, each girl's growth curve can be described with an intercept and two slopes, one slope for the changes in percent body fat before menarche, another slope for the changes in percent body fat after menarche. We fit the following linear mixed model using (restricted) maximum likelihood estimation, assuming the distribution of the random terms is normal:

$$Y_{ij} = \beta_0 + \beta_1 t_{ij} + \beta_2 (t_{ij})_+ + b_{0i} + b_{1i} t_{ij} + b_{2i} (t_{ij})_+ + \varepsilon_{ij}$$

where t_{ij} denotes the time, relative to menarche (i.e., before or after menarche), of the jth measurement on the ith subject (with $t_{ij} = 0$ at menarche), and $(t_{ij})_+ = t_{ij}$ if $t_{ij} > 0$ and $(t_{ij})_+ = 0$ if $t_{ij} \leq 0$. The three random effects are assumed to have a multivariate normal distribution, with zero mean, and unstructured covariance matrix.

Table 1 presents the fixed effects estimates of the overall mean curve, the intercept, and two slopes, before (β_1) and after menarche ($\beta_1 + \beta_2$). Notice that this approach allows us to estimate mean percent body fat at menarche (when $t_{ij} = 0$), β_0, even though few if any girls were actually measured then. From Table 1 the model-based estimate of the mean percent body fat at menarche is approximately 21%. Regarding the main question of scientific interest, based on the magnitude of the estimate of β_2, relative to its standard error, there is a significant difference between the slopes before and after menarche. The estimate of the population mean premenarcheal slope is 0.42 and indicates that the annual rate of body fat growth is less than 0.5%. In contrast, the estimate of the population mean postmenarcheal slope is 2.46(0.417 + 2.047) and indicates that the annual rate of body fat growth is approximately 2.5%, almost six times higher than the corresponding rate in the premenarcheal period.

The covariance matrix for the random effects has six parameters, three parameters for the variances of the random intercepts and slopes, and three parameters for their covariances. Estimates of the variance and covariance parameters are given in Table 2. Much of the subject-to-subject variability is contained in the intercept. The covariance between a subject's intercept and postmenarche slope is negative, suggesting that girls with higher body fat at menarche, tend to gain less after menarche. Results from the mixed model analysis also allow us to estimate values of the variances and covariances for measures of percent body fat at arbitrary times; this is illustrated in Table 3 for 4 years pre- and postmenarche. Here we see a decline in variance over time; in addition, the strength of the correlation declines with increasing time separation. The latter feature of the correlation is not uncommon in longitudinal studies.

Table 1 Estimated linear regression coefficients (fixed effects) and standard errors for the percent body fat data

Variable	*Estimate*	*SE*	Z
Intercept	21.361	0.565	37.84
Time	0.417	0.157	2.65
$(\text{Time})_+$	2.047	0.228	8.98

Table 2 Estimated variances and covariances of the random effects and standard errors for the percent body fat data

Parameter	*Estimate*	*SE*
$\text{Var}(b_{0i})$	45.941	5.739
$\text{Var}(b_{1i})$	1.631	0.433
$\text{Var}(b_{2i})$	2.750	0.964
$\text{Cov}(b_{0i}, b_{1i})$	2.526	1.219
$\text{Cov}(b_{0i}, b_{2i})$	−6.110	1.873
$\text{Cov}(b_{1i}, b_{2i})$	−1.751	0.598
$\text{Var}(\varepsilon_{ij}) = \sigma_\varepsilon^2$	9.473	0.544

Table 3 Estimated marginal correlations (on the lower diagonals) among repeated measures of percent body fat between 4 years pre- and postmenarche, with estimated variances along the main diagonal

Time in years (relative to menarche)								
−4	*−3*	*−2*	*−1*	*0*	*1*	*2*	*3*	*4*
61.3

0.47	0.54	0.60	0.64	0.66	0.70	0.74	0.76	40.8

Summary

Linear mixed models are a natural extension of classical linear regression models that allow for the incorporation of random effects to account for the correlation among repeated measures on the same individual or cluster. The widespread use of mixed models in so many areas of application in the social and behavioral sciences can be explained in part by the great flexibility they offer in modeling the correlation in *unbalanced* designs and by the increasing availability of statistical software for implementing mixed model methods. This article has described a general linear mixed model for longitudinal and cluster-correlated Gaussian data. When the outcome is discrete (e.g., binary, ordinal, or a count) rather than continuous, linear mixed models are no longer appropriate for relating the mean response to covariates. Instead, there are extensions of generalized linear models (e.g., logistic regression) for analyzing cluster-correlated discrete data known as generalized linear mixed models (e.g., *see* Generalized Linear Mixed Models). These models account for the correlation among the repeated

measures via the incorporation of random effects into generalized linear models (e.g., logistic regression models with randomly varying intercepts). Generalized linear mixed models extend in a natural way the conceptual approach represented by the linear mixed models discussed in this article.

Abstract

Linguistic anthropology is a branch of both anthropology and linguistics, aiming to document and study the use of language as a social, cognitive, communicative, and cultural tool. The viewpoint that guides most of the work in the field is the premise that language structures reflect cultural concepts which, in turn, reflect social and communicative structures. This article presents the background and basic notions of linguistic anthropology and then looks at its areas of research including ethnosemantics, conversation, texts, and dialects, among others.

Introduction

Linguistic anthropology (LA) is an approach to the study of language that focuses on the relation between language, society, and culture. It is considered by some to be a branch of general linguistics, by others a branch of anthropology, and by still others as an autonomous discipline. Its roots are in the foundation of linguistics as a science in the nineteenth century after English scholar Sir William Jones (1786) remarked that Sanskrit, Persian, Greek, and Latin sprang from the same source and thus belonged to the same 'language family.' This suggested that languages shared structural features and evolved over time from older forms to develop their own distinct forms. A full-fledged science of language emerged after Swiss philologist Ferdinand de Saussure (1916) provided a theoretical framework for studying language as a system in his book, titled *Cours de linguistique générale*, which was published posthumously from the notes taken by his students at the University of Geneva.

Saussure's framework came under the rubric of structuralism (paralleling developments in psychology and other emerging human and social sciences at the time). In Europe, it was adopted and elaborated by a number of linguists who congregated in the Czech city of Prague, known as the Prague Circle, in the 1920s and 1930s. Structuralist linguistics became the basis for studying indigenous North American languages at Columbia University in the first two decades of the twentieth century under the leadership of Franz Boas (1940), who founded the *International Journal of American Linguistics* to publish research on the languages native to North, Central, and South America in 1917. With the foundation of the Linguistic Society of America in 1924, and its journal, *Language*, a year later in 1925, linguistics developed into a flourishing discipline with a basis in anthropological methods. It received its first comprehensive treatment in America with Leonard Bloomfield's *Language* (1933).

In 1957, the American linguist Noam Chomsky argued that any serious scientific approach to language would have to focus on why all languages reveal a similar pattern for constructing their grammars, independently of culture. His perspective became a dominant one, and still has a large following. Chomsky's claim has always been that cultural and communicative phenomena are separate from strictly grammatical ones (Chomsky, 2002). Since the late 1960s, various arguments have come forward to challenge this stance, reinstating the original view of Boas and others that grammar develops in relation to communicative and cultural forces, not separately from them. This approach came to be called *anthropological linguistics* (to distinguish it from *theoretical linguistics*) and was renamed *linguistic anthropology* by Dell Hymes (1962). To this day, the two terms are used interchangeably, although the latter is now more widespread. LA is a thriving field today, sometimes overlapping with so-called *cognitive linguistics*, which focuses on the relation between language, cognition, and culture. The most prominent figure in the latter approach is the American linguist George Lakoff (1987). Lakoff's main argument is that the conceptual backbone of language is figurative and thus tied to the specific historical experiences and worldviews of the users of language. He cites, as an illustration, the emergence of grammatical gender categories in an indigenous Australian language called Dyirbal. In European languages, the gender of a noun is often unpredictable from its meaning and, thus, is typically thought to be arbitrary. For example, the word for 'table' is masculine in German (*der Tisch*), feminine in French (*la table*), and neuter in Greek (*to trapézi*). But in Dyirbal this is hardly the case. One of its four gender categories includes all nouns pertaining to *women*, all those pertaining to *fire*, and all those indicating things that are *dangerous* (snakes, stinging nettles, and the like). Gender assignment is culturally based, being determined by Dyirbal's cultural worldview.

Background

In the seventeenth and eighteenth centuries, the first surveys of languages were conducted in order to determine which features of language were universal and which were specific, independent of the cultures that spoke them. A group of French scholars, known as the Port Royal Circle, put forward the idea of a universal faculty of language that provided every different language with the same set of principles from which they could construct their individual grammars. Opposing this stance, the German scholar Wilhelm von Humboldt (1836) viewed language as springing from the historical needs of its speakers, conditioning how subsequent

generations came to view reality. An example of this is the phenomenon of color. The color names developed by a particular group of people are those that they have required for their own functional purposes. Given the fact that there are millions of visual discriminations that the eye can make, languages would have to otherwise come up with just as many words to encode them. So they name only those color discriminations that are useful and meaningful to them. It is true that there are patterns in how color categories have evolved across time and across cultures (Berlin and Kay, 1969), but this fact in no way opposes the fact that specific color vocabularies influence how people view the spectrum. Humboldt (1836: p. 43) summarized this line of reasoning as follows:

> The central fact of language is that speakers can make infinite use of the finite resources provided by their language. Though the capacity for language is universal, the individuality of each language is a property of the people who speak it. Every language has its *innere Sprachform*, or internal structure, which determines its outer form and which is a reflection of its speakers' minds. The language and the thought of a people are thus inseparable.

The disciplines of linguistics and anthropology have always overlapped considerably. Boas founded the first major department for the teaching of anthropology in 1899 at Columbia University in New York City, making linguistics the core of the discipline. The break between linguistics and anthropology came with Chomsky (1957). Boas amassed data on the Kwakiutl, a native society on the northwestern coast of North America, showing how the grammar and vocabulary of their language served their needs perfectly. Boas also introduced *ethnography* as the central method of linguistics. Ethnography is the study of some cultural phenomenon through systematic observation, consisting primarily in gathering empirical data by observing a group or society with interviews, questionnaires, and interaction.

Boas's student Edward Sapir (1921), and later Sapir's own student Benjamin Lee Whorf (1956), elaborated the Humboldtian view, suggesting that specific languages filter the reality perceived by their speakers, presenting them with differential cognitive slices of the same reality. Their approach generally falls under the rubric of *linguistic relativity*, the *Sapir–Whorf Hypothesis*, or simply the *Whorfian Hypothesis* (WH). The WH posits that languages predispose their speakers to attend to certain concepts (rather than others found in different languages) as being necessary, without blocking understanding between speakers of different languages. While this orientation is, and always has been, controversial, it has generated a lot of interesting findings, debates, and applications to the present day (Hoijer, 1954; Hill and Mannheim, 1992; Sidnell and Enfield, 2012; Danesi, 2013). Most importantly, it brought the powerful role of figurative language in cognition and culture to the forefront (Pollio et al., 1977; Ortony, 1979; Honeck and Hoffman, 1980; Lakoff and Johnson, 1980, 1999). Even a simple gustatory object like a piece of chocolate has symbolic status that is connected to love through the channel of cultural metaphors such as *love is a sweet taste*. These are also imprinted in common utterances such as *She's my sweetheart; They went on a honeymoon*; and so on.

Research Topics

The research agenda in LA is a vast and varied one. What ties all the work together is the focus on the language–culture nexus and in the many ways that it manifests itself in everyday social phenomena such as vocabulary choices and conversations. In the earliest research efforts, the focus was on how cultural classification and language interrelated because, as Sapir (1921: p. 75) clearly maintained, reality is organized cognitively by the specific categories of the language that speakers are familiar with:

> Human beings do not live in the object world alone, nor alone in the world of social activity as ordinarily understood, but are very much at the mercy of the particular language system which has become the medium of expression for their society. It is quite an illusion to imagine that one adjusts to reality essentially without the use of language and that language is merely an incidental means of solving specific problems of communication or reflection. The fact of the matter is that the "real world" is to a large extent unconsciously built up on the language habits of the group.

With different kinds of research paradigms and techniques, work in this area, known more specifically as *ethnosemantics*, continues to this day. For instance, John Lucy (1996) studied the effect of grammar on memory tasks on English and Yucatec (a Mayan language) speakers, focusing on the presence of a dichotomy between the two languages: English requires a plural marker for count nouns (*dog – dogs*); Yucatec does not, except for a small number of nouns. Lucy presented pictures of Yucatec village scenes to both speakers and asked them to perform recall tasks. He found that English speakers paid attention to the number of animate beings and objects, but ignored number for substances; Yucatec speakers paid attention to number only for animate beings. The experiment showed that grammatical categories did indeed condition how people recalled the world.

Overall, this line of inquiry has shown that, once classified, 'reality' is an ideological system passed on through language forms to subsequent generations. Of course, they can change their views of the world any time they want, by simply inventing new words for new realities that are meaningful to them. This is why languages change over time.

Identity, Socialization, and Ideology

Research in LA today has gone far beyond its ethnosemantic origins. One area concerns how language, socialization, and identity are interlinked. Don Kulick (1992), for example, conducted ethnographic work in a village in Papua New Guinea called Gapun, which spoke Taiap, a language known only to the villagers. He was able to document how that language, although spoken by a small group of people, constituted a source of pride, constituting an 'index' (a key) to identity and thus allowing the villagers to feel and claim autonomy from Tok Pisin speakers (the pidgin language spoken by others). Taiap allowed the villagers to express shared values, especially during ritualistic verbal performances that garnered a high level of emotional resonance.

Language as a socializing agent has always been at the core of LA. Prominent in this subfield is the work of Elinor Ochs and Bambi Schieffelin (Ochs and Schieffelin, 1984; Ochs, 1988; Schieffelin, 1990, 1995, 2000, 2002; Ochs and Taylor, 2001), who have looked extensively at how socialization is, essentially, a linguistic-adaptive process – allowing individuals to participate in a community and its culture in a meaningful way. Children are socialized into belief systems, historical content, and so on with and through oral narratives. In one study (Ochs and Taylor, 2001), it was shown that the narratives told (informally) at dinner time in white middle-class households in southern California typically presented role structures, gender distinctions, and other socializing and enculturation themes to family members.

Michael Silverstein's work on the role of language in the formation and expression of ideologies has made an impact within both LA and other branches (Silverstein, 1976, 1979, 1985; Rumsey, 1990; Kroskrity, 1998). Silverstein defines *ideology* as a shared body of commonsensical notions about the nature of the world. He rejects the Marxist view that ideologies create 'false consciousness' deriving from the perception in capitalist societies that material objects and institutions induce people to experience social relations in terms of the amount of capital they possess and the things they wish to purchase. Silverstein argues that, on the contrary, the form of language used by a society has more impact on ideological formations than does the socioeconomic system in place. Ideology is really 'ideation' or the formation of ideas connected to the semantic system of a language. The evolution of this system is not directly tied to political or economic forces but mirrors them, encodes them, and then filters perceptions about them. In a similar vein Alessandro Duranti (2003) has argued that language creates an 'exemplary center' or 'social space' of political and ritualistic power, not a hegemonic one. This space constrains the types of speech and relations that are relevant to a specific group. In it, refined speech, for example, is hardly part of political and economic ideology, but rather a tool in a broader system of socialization. At play in all this are semiotic forces, such as iconicity and indexicality. The former is essentially mimetic or imitative behavior that reflects a continuum or scale of prestige and power, and the latter is a relational form of behavior and understanding that reveals who a speaker is and what he or she aspires to be as well as which values he or she espouses.

Text Structure

Starting in the late 1960s, some researchers in LA started putting the focus on the role of conversations, discourses, and texts in shaping grammar. British linguist Michael Halliday (1985), for example, showed that some parts of speech are 'text-governed' structures, not sentence-based ones. Consider, for example, the following stretch of conversation, which has no pronouns in it. Even though it is completely understandable, we nevertheless perceive it as being awkward:

Speaker A: Alex is a nice young man.
Speaker B: Yes, Alex is a nice young man.
Speaker A: But Alex always likes to talk about Alex.
Speaker B: Yes, Alex does indeed always talk about Alex.

The more socially appropriate version of the conversation is one where pronouns are used instead:

Speaker A: Alex is a nice young man.
Speaker B: Yes, he is.
Speaker A: But he always likes to talk about himself.
Speaker B: Yes, he does indeed always talk about himself.

The use of pronouns is thus conversationally 'systemic'; it connects the various parts of the conversation, linking them logically like a trace device. In other words, pronoun choice is tied to text structure, not grammar, and is part of the style that is appropriate in a specific language. Some cultures encourage repetition; others, like English culture, do not. The repertoire of language forms available to a group of speakers thus does not form an arbitrary system of use; that is, the forms are not constructed artificially but in tandem with their use. As William Dwight Whitney emphasized, a precursor to this kind of approach in America (Shuy, 1997: p. 12), speakers of a language are extremely sensitive to socially coded textual cues, using them to evaluate other speakers and to present themselves in specific situations. In societies across the world, these cues are used for the whole array of social meanings that we see as critical.

Social Markers

The role of language in gender distinction is another major area of research – an area that has led to the entrenchment of the notion of *social markers*. In Japanese the word for 'stomach' is *hara* for men, but *onaka* for women, probably alluding to the fact that, biologically, the two stomachs are different. In Koasati (an indigenous language spoken in Louisiana), men say *lawawhol* to refer to 'lifting,' while women say *lakawhos*, perhaps implying that the lifting abilities of the two sexes are different. The point to note here is that the use of one or the other word according to the gender of the speaker is considered to be socially important. In some languages, such as the one spoken on the Island of Carib in the West Indies (Taylor, 1977), there exist a large number of prescribed doublets (pairs of words with the same meaning) that are marked for gender use. So, the word for 'sun' is *kachi* or *hueyu*, spoken respectively by the women and the men. Doublets are as important as differential modes of dressing, hairstyle, and other signifying resources that are used to keep the genders distinct socially.

Doublets are examples of 'social markers,' delineating those differences that are considered to be relevant or historically important to a community. Analogous markers are found across the whole spectrum of human relations, from politeness protocols to class structure. The misuse of one or the other would be perceived as a breach of social etiquette or as a sign of anomalous communication. It would be considered rude to address a superior at work with an informal mode of speech (unless the superior permits it); and it would be aberrant or strange to address a close friend with titles. Class differences, like gender ones, are mirrored in linguistic forms called *registers*. In the traditional Javanese society of Indonesia, for instance, different social classes are expected to utilize a distinct register of speech (Errington, 1988). At the top of the social hierarchy are the aristocrats; in the middle the townsfolk; and

at the bottom the farmers. The highly formal register is used by aristocrats who do not know one another very well, but can also be used by a member of the townsfolk if he or she happens to be addressing a high government official. The mid formal register is used by townsfolk who are not friends, and by farmers when addressing their social superiors. The low register is used by farmers among themselves, or by an aristocrat or town person talking to a farmer, and among friends on any social level. It is also the register used to speak to children of any class.

Change in social markers involves change in society as a whole. The use of the masculine gender in English was not only a simple grammatical device, but it reflected social inequalities. Terms like *chairman* and *spokesman* revealed how the English language predisposed its users to view certain social roles in gender terms. English grammar was organized from the perspective of those at the center of the society – the men. In matriarchal societies the reverse seems to be true. Investigating grammatical gender in the Iroquois language, Alpher (1987) found that in that language the feminine gender was the default one, with masculine items being marked by a special prefix. Alpher related this to the fact that Iroquois society is matrilineal. The women hold the land, pass it on to their heirs in the female line, are responsible for agricultural production, control the wealth, arrange marriages, and so on. Iroquois grammar is clearly organized from the viewpoint of those at the center of that particular society – the women.

Conversation and Discourse

Research interest within LA with conversations and discourse overlaps somewhat with the branch often called *pragmalinguistics* or *pragmatics*. Conversation analysis (CA) surfaced in the 1980s and 1990s, becoming a useful tool that both anthropological linguists and sociolinguists use commonly. CA aims to show that how people talk not only taps into a system of implicit social rules and patterns, but also shapes and changes the formal language system itself. Hutchby and Wooffitt (1998: p. 14) articulate the goal of CA as follows:

> CA is the study of recorded, naturally occurring talk-in-interaction. Principally, it is to discover how participants understand and respond to one another in their turns at talk, with a central focus being on how sequences of interaction are generated. To put it another way, the objective of CA is to uncover the tacit reasoning procedures and sociolinguistic competencies underlying the production and interpretation of talk in organized sequences of interaction.

The tacit reasoning procedures to which Hutchby and Wooffitt refer are manifestations of what Dell Hymes called *communicative competence* in 1971, a term that came forward to complement the notion of *linguistic competence* – a distinction that goes back to Saussure's (1916) notion of *langue* (linguistic competence) and *parole* (knowledge of how to use language). Hymes suggested that knowing how to use language during conversation is as systematic as knowing the rules of the grammar of the language being employed. Recalling the work of Charles Morris (1938), this line of inquiry shows that communication and grammar form an integrated system. In CA the target of analysis is to live among, or simply to interview (and/or record and tape), subjects in order to get not the singular object of speech (word or sentence), but the conversational text. The research has shown that conversational structure is constrained by factors such as situation, social conventions, and style (Sacks et al., 1995). Above all else it is sensitive to *sequence* structure. We anticipate how the forms in a text relate to each other and cohere sequentially into a message-making system.

Various theories have been put forward to explain the social nature of conversations. Erving Goffman (1959, 1981) referred to them as strategies in the 'framing' of identity, whereby language is used to fit a situation deliberately by speakers. Another theory is that conversation is intended to play a group function, so as to impart a sense of togetherness among interlocutors as well as a sense of security. As Robin Lakoff (1975) has discussed, speakers will even refrain from saying what they mean in some situations in the service of the higher goal of identity preservation or the conservation of group solidarity.

The notion of speech acts also has become useful in this domain of research (Austin, 1961). This concept has provided a taxonomy for pigeonholing utterances in terms of their social functions. A speech act is an utterance that aims to bring about, modify, curtail, or inhibit some real action. The utterance 'Be careful,' for instance, would have the same effect as putting a hand in front of someone to block him or her from crossing the road carelessly. The statement 'I sentence you to life imprisonment' uttered by a judge has the same effect as marching the accused directly to prison and locking him or her up. The interesting thing about speech acts is that they influence the composition and structure of sentences, showing again that linguistic and communicative competence intersect constantly in interactions.

There are various versions of speech act theory. The central idea in all of these is that grammatical and lexical structures allow people to do things with words. The main types of speech act are as follows:

- *locutionary*, the act itself of saying something (*Mary said, 'I can't come out tonight. It's my birthday'*);
- *illocutionary*, an utterance that indicates the speaker's purpose in saying something (asking and answering questions, giving information, assurance, identifying, etc.) (*Mark protested against what you said*); and
- *perlocutionary*, an utterance that produces sequential effects on the feelings, thoughts, or actions of interlocutors (*Lucy stopped me, bringing me around*).

Each of these main categories can be broken down further (Searle, 1969):

- *representatives*, utterances that commit the speaker to something: stating, concluding, representing, deducing;
- *directives*, attempts by the speaker to get an interlocutor to do something: command, offer, invite, ask, request, beg, permit, dare, challenge;
- *commissives*, utterances committing the speaker to some future course of action: promise, pledge, threaten;
- *expressives*, utterances revealing the psychological state of the speaker toward something: thank, congratulate, apologize, condole, deplore, welcome; and

- *declarations*, utterances connecting propositional content (assumptions in the utterance) to reality: appoint, resign, nominate, pronounce.

The actual structure and contents of conversations are connected to *discourse* or larger linguistic frames of reference. The term refers to the unconscious use of language to connect people or groups in terms of shared values, worldviews, beliefs, biases, and so on. Discourse is typically characterized by keywords that appear frequently in relevant conversations and by other interlinked structures such as logical argumentation styles, conversational styles, and so on (Tannen, 1989, 1993; Fairclough, 1995; Van Dijk, 1997; Scollon and Wong Scollon, 2001).

Schools, corporations, universities, the media, and other groups all develop discourse styles that determine how members within the groups speak to each other. As Russian literary critic and semiotician Mikhael Bakhtin (1981) argued, discourse styles are the products of unconscious processes of socialization and ideological reproduction. They imply an implicit knowledge system based on cultural presuppositions and a shared evaluation of the meanings of a context where speech is used. Discourse thus manifests itself in specific kinds of performative styles. Religious rites, prep rallies, political debates, and formal academic lectures, among others, are anchored in such styles, either traditionally worded or specifically composed for the occasion. Discourse creates allegiances and reinforces identity functions of a group (Hymes, 1975; Bauman, 1977; Wilce, 2006).

Other Traditional Areas

A traditional area of interest within LA, which overlaps with both sociolinguistics and historical linguistics, is the study of dialects or regional, social, or ethnic varieties of a language. By this definition, the English taught in school is only one dialect of contemporary American English, usually called Standard American English. The questions that relate dialect study to social structure include:

- Which dialect is perceived as more prestigious than others and why? This type of study comes under the rubric of *diglossia*.
- Do dialectal differences in artistic venues and expressive forms (such as hip-hop) reflect broader discourse and social tendencies, including political ones?
- Which local pronunciations show local allegiance?
- What is the role of slang and other forms in the construction of identity?

There are many societies where more than one language is used and even taught at school. The study of such phenomena and their social implications has always been an intrinsic part of LA. Spanish-speaking communities in the United States, for example, develop differential cultural realities vis-à-vis the broader English-speaking culture. This produces a whole series of issues that can be studied systematically in LA. Hispanics share many of the traditional values claimed by Americans, but they are by and large also proud of their Latin American heritage. Many Hispanic Americans feel that they should not lose contact with their cultures of origin or their language, seeking to be bicultural and bilingual. Many hope that their cultures will someday be accepted as being part of American culture.

In early school bilingual programs serving Hispanics, students were taught in Spanish in such basic subjects as mathematics and science. Meanwhile, they studied English as a second language. When they were ready, they transferred to classes taught only in English. By the 1990s, many schools had replaced that transitional approach to education with the two-way bilingual approach, combining native Spanish speakers with English-speaking students in all classes. The students progressed together through the grade levels, with some subjects taught in Spanish and others in English. The participants helped one another learn both the new language and the subjects being taught. Since bilingual education began, it was controversial. Critics claimed that it encouraged students to rely too much on Spanish. Supporters argued that it never received enough support. They claimed that lack of funding and of teacher-training programs hindered such education. In 1998, California voters approved a controversial measure requiring that all public school classes be taught only in English. But bilingual classes remained available in California to students whose parents or school boards requested them and to students with special needs. Today, most educators see bilingual education as an advantage, thanks in large part to the findings of LA.

The broader issues of bilingualism and multilingualism are also part of LA. Language change spreads through networks of people who talk with one another. Tight-knit groups that keep to themselves tend not to promote change. People can live next door to one another and not participate in the same network. In the United States, English became the popular language from coast to coast, largely replacing colonial French and Spanish and the languages of Native Americans. In the Caribbean and perhaps in British North America where slavery was practiced, Africans learned the English of their masters as best they could, creating a language for immediate and limited communication called a pidgin. When Africans forgot or were forbidden to use their African languages to communicate with one another, they developed their English pidgin into their native tongue. A language that develops from a pidgin into a native language is called a Creole. African American Vernacular English may have developed this way.

The above discussion suggests that people form social networks, which can be loose or tight depending on how members interact with each other. For instance, an office or factory may be considered a tight community because all members interact with each other. A large course of students would be a looser community because students may only interact with the instructor and maybe a few other students. A multiplex community is one in which members have multiple relationships with each other. For instance, in some neighborhoods, members may live on the same street, work for the same employer, and even intermarry.

Basil Bernstein (1971), a well-known British linguist, has distinguished between *elaborated* and *restricted* codes. These are ways in which speech varieties reflect, and are classified, as patterns in different social classes. Bernstein claimed that

members of the upper and middle classes had ways of organizing their speech into *codes* that were fundamentally different than how the lower classes did. The former were *elaborated* and the latter *restricted*. Codes allow people in classes to bond and to make differentiations that are crucial to them. In Britain he saw a basic social dichotomy – restricted codes emphasized the 'we' as a social group, whereas in elaborated codes the emphasis is on the 'I' and thus on the individual. Restricted codes thus fostered greater group adhesion. He also studied how children with a restricted code struggled at school where the elaborated code is the default form of language.

Elaborated codes are more in sync with standard forms of the language. It is generally assumed that nonstandard language is low-prestige language. However, in certain groups, such as traditional working-class neighborhoods, the standard language may be considered undesirable in many contexts. This is because the working-class code is a powerful in-group marker, and especially for nonmobile individuals, the use of nonstandard varieties (even exaggeratedly so) expresses neighborhood pride and class solidarity. There will thus be a considerable difference in the use of nonstandard varieties when going to the pub or having a neighborhood barbecue (high), and going to the bank (lower) for the same individual.

New Areas

More and more, the tools of LA are being applied to examine the evolution of linguistic forms in cyberspace. The concepts of register and style, to mention but two, are being revamped by the study of communications in online media (Crystal, 2006; Baron, 2008).

Studies such as those by Farman (2012) on Mobile Interface Theory and Papacharissi (2011) on the recreation of the Self in social media are leading the way in showing how to apply traditional linguistic and ethnographic methods to cyberspace. Facebook offers a range of new registers that allow for a new way of framing speech, including messaging, commenting, posting, as well as nonverbal modalities such as photos, sharing links, the 'like' button, and so on. Studying the 'post + commenting' section, which users treat as a quasi-conversational space, can provide new insights into older theories about sequential unfolding, turn-taking, coherent exchanges, and so on within CA. The theoretical significance of this research is the exploration of how humans maintain social order through writing and reading practices in cyberspace.

Communication that involves more than two parties is typically characterized by assigning and adopting roles, a phenomenon that Goffman (1981) called 'footing.' These roles are partly achieved in the conversational situation rather than being something that preexists ritualistically. On Facebook, the number of potential participants in a 'commenting event' tends to be much higher than in regular conversational interaction, and thus managing Facebook conversations changes the structure of footing. Anyone on a user's friends' list can leave a comment at any time, whereas in face-to-face conversation, only those who can hear another's voice will be able to participate. A different set of conversational skills is thus emerging on Facebook and other social media sites and it is starting to show that the traditional theories in LA need adaptation and elaboration.

Concluding Remarks

Since LA focuses on how language is used and on how use influences worldview and social relations, ultimately it allows us to gain valuable insight into the overall enigma of language. The goal of the puzzle-solver is to figure out how language fits into human life and what it does to that life. The anthropological linguist seeks to figure out how the bits and pieces (sounds, words, and so on) cohere into the organism of language. But having described how they do, we are still left with the dilemma of why such an organism came into being in the first place. The research in LA has shown that diversity is the norm, but that diversity only reflects differentiated attempts to solve similar problems across the world. It shows how we go about tackling the same problems of classification, understanding, and communication coming up with different solutions according to situation, time, and place. The fact that we can understand each other nonetheless shows how much we are really all one race, equal and seeking similar objectives and outcomes to the experience of existence.

Linguistic Approaches to Agrammatism

Alan Beretta, Michigan State University, East Lansing, MI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article discusses linguistic approaches to agrammatism. First, we consider the possible contributions that the study of agrammatism can make to an understanding of the ways a brain computes language. To understand how a brain computes language, we minimally need to know something about language and something about language processing so that we can pose coherent questions to a brain. We consider in some detail how one well-known model of agrammatism accommodates what we know about language and language processing and find that the basic challenges have not been met. We compare this to a developing range of inquiry into agrammatism that is potentially more useful in moving the larger project forward.

Introduction

Agrammatism is a somewhat general term that is used to refer to an aphasic production deficit that results in slow, effortful speech in which functional categories, such as tense markers, while they might make an occasional appearance, are often missing or wrongly substituted. This characterization is traditionally associated with Broca's aphasia, as the following exchange with a patient suggests:

Patient: Farmer, uh, Ohio, farm, soy beans and corn, uh, 400 acres, yeah, miles and miles and miles, uh 32 years ago, me, supervisor
Q: Do you still farm?
Patient: No, well, uh, lawnmower (laughs).
Q: Your children, what do they do?
Patient: Uh, uh, Harry, uh, Minnesota, uh, Minneapolis, and uh, Indians, dead, oh, many, 200, 300, 400, 500, dead.
Q: What does Harry do with Indians?
Patient: Grounds, uh, Indian grounds.
Q: A reservation?
Patient: No, uh, die, uh, goddammit.
Q: Oh, burial grounds?
Patient: Yeah! Yeah!
Q: Harry works in burial grounds. What job does he do?
Patient: Uh, uh, oh boy, arrow, uh, Indian pieces.
Q: He looks for these things?
Patient: Yeah! Yeah!
Q: So he's an archaeologist?
Patient: Yeah! Yeah!

This extract also supports another traditional observation, namely, that Broca's aphasic patients have preserved comprehension. As Broca himself noted a century and a half ago, they operate with full intelligence; they hear and understand everything that is addressed to them perfectly (1861).

Inquiry into unimpaired sentence production lags behind inquiry into unimpaired sentence comprehension; so agrammatic comprehension if it were not in fact perfectly intact, would have the greater potential to make a useful contribution to an understanding of normal parsing. As it turned out, a landmark study in the 1970s (Caramazza and Zurif, 1976) revealed that Broca's aphasics could not understand certain types of sentences once their 'full intelligence,' including world knowledge, conversational context, and so forth, was rendered irrelevant and they were forced to rely on their knowledge of sentence structure to determine who was doing what to whom. On a sentence-picture matching task (in which they point to one of two or three pictures that best matches a sentence they have just heard), they could understand a passive sentence, such as *the ball was kicked by the boy*, because they know that boys can kick balls but not the reverse, but if the sentence was reversible, such as *the girl was chased by the boy*, they could not tell who was doing the chasing. In semantically reversible sentences, they could understand actives, but not passives; and they could understand subject relative clauses but not object relative clauses.

Even if this asymmetric agrammatic comprehension had been recognized in Broca's time, he would not have been able to say why such a pattern should have occurred. The problem could not be addressed in Broca's time because there was no theory available that could make sense of the observations. In fact, Broca was acutely aware of this: "the biggest obstacle hindering progress in this part of physiology [cerebral localization] results from the insufficiency and uncertainty of the functional analysis, which must precede the search for identifying organs for each function. Science is so behind in this respect, that it has not even found its foundation yet …" (1861/2006, p. 294). Broca did not envisage that this need for theory applied to language; he considered a notion such as 'spoken language' to be a neatly circumscribed, self-evident function not requiring any explanation. It was other faculties of mind that were in need of theory. However, if we take up Broca's realization that we cannot relate brain states to some function unless we know something about that function, and if we assume – surely uncontroversially – that the only relevant knowledge is theoretical, then we might expect to benefit from attention to a theory of language in seeking to understand the nature of Broca's aphasia. We might also expect to benefit from an appreciation of how language conspires with other faculties involved in comprehension, such as memory, that is, a theory of sentence processing.

Fortunately, we have an increasingly good appreciation of the factors that affect sentence processing and we have an increasingly good understanding of the nature of the human language faculty. In light of this, how might studies agrammatic comprehension contribute to what is known about how a brain processes the sentences it is confronted with? What has been accomplished to date? What challenges lie ahead? Let us address each of these questions in turn.

What Contribution Can Inquiry into Agrammatic Comprehension Make?

To answer this question, it is useful to step back and view the issue from a broader perspective and ask what the study of brain and language, that is, neurolinguistics could contribute. If we had no theory of language, then we would be reduced to posing pretheoretical, and therefore incoherent, questions to the brain. But at least since Chomsky (1981), understanding and evidence have reached a point where we can refer to a theory of language. Similarly, the interplay of hypothesis and experiment in neurobiology, at least since the work of Hodgkin and Huxley (1952a, b, c, d, e), has attained a level of explanation that can reasonably be referred to as a theory of brain. The problem is that our best theory of language and our best theory of brain do not have a single property in common. It is what Chomsky (1995, 2000) has called a theory unification problem, a standard kind of problem throughout the history of science, but that is not to minimize the challenge. Unifying our theories of language and brain currently seems hopelessly remote.

We know how we could find out more. We could proceed invasively, as is routinely done in inquiries into brain function with nonhuman animals. Single cells in precisely identified regions of normally functioning intact brains are recorded to see if they responded to specific stimuli. To complement such findings, a whole range of techniques for inactivating those regions are deployed. For example, in avian song research, tissue from a target region might simply be ablated; or toxins introduced to block sodium channels, thus preventing cells from firing. Or, an antagonist to a particular neurotransmitter might be injected into the region, which has the effect of blockading receptors for that neurotransmitter, but leaving the receptors for other neurotransmitters unaffected. Or, brain regions might be systematically cooled, which has the effect of slowing function, allowing localization of behaviors with structures on many timescales, such as the motif, syllabic, and subsyllabic structures of zebra finch song (Long and Fee, 2008). The range, precision, and discriminability of the techniques available to research on intact and impaired brains in research on birds have yielded a great deal of knowledge in a very short period of time.

But for obvious reasons, they are not available for research on humans; there can be no direct electrical stimulation, no ablation of tissue, no severing of fibers, no single-cell recording, no pharmacological interventions to temporarily disable either pre- or postsynaptic neurons, and no cooling to analyze complex temporal dynamics. There can be no research at the cellular or molecular levels at all (except adventitiously, and in a very limited way, when patients have electrodes implanted for clinical reasons prior to surgery, for example, for intractable epilepsy).

So, the problem that confronts us is twofold: first, current theories of language and brain share not a single property; and second, language function, unlike, say, vision, in core respects is not available in other species, so we cannot avail ourselves of the invasive techniques that would allow inquiry at cellular and molecular levels.

With regard to the second problem, we have had to be more subtle. The tools at our disposal are the various noninvasive imaging technologies with which we attempt to identify regions involved in language function, or the timing of those functions, in living brains; and opportunistic use is made of naturally occurring brain damage that affects language function in some way, that is, in aphasia.

Addressing the first problem, the remoteness of language – brain theory-unification, it is a little less obvious how to proceed. One approach would be to let linguists and neurobiologists get on with the job or developing better and better theories and return in 50 years to see if some means of unification presents itself. And for a satisfying resolution on a par with Pauling's unification of chemistry and physics, we may have to wait for one theory or the other to undergo a parallel to the quantum revolution. But resolution might be arrived at differently. One possible approach is to target intermediate levels of unification, and the most obvious is for neurolinguists to deploy not only linguistic theory but also whatever understanding has been gained in psycholinguistics. Seeking to integrate what we know about the nature of language and what we know about language processing is major challenge but one that is at least realistic in the medium term; indeed many researchers have been actively investigating the relation. Precisely how to envisage the relation varies widely among individuals, and it is beyond the scope of this article to discuss the issues involved, but see, for example, Phillips (2012) and Phillips and Lewis (2013) for relevant discussion. For current purposes, it is sufficient to note that the relation between linguistics and psycholinguistics is firmly on the agenda, as it is in this respect that syntactic approaches to agrammatism may have more to offer in the coming years.

What Has Been Accomplished to Date?

In what follows, I will examine just one model of agrammatic comprehension. It is worth examining one model in some depth rather than cursorily describing several (and there are many) because much can be learned from the ways in which it has failed conceptually and empirically and where progress may be made. We will see that it runs into serious empirical problems, but more interestingly, we will see that it avoids the constraints of linguistic theory and uses theory-free strategies to accommodate anomalies. In addition, we will see that it does not set itself up in relation to normal, unimpaired processing. Seeing these limitations clearly ought to make it easier to see an alternative approach to agrammatic comprehension data.

The Trace-Deletion Hypothesis

In discussing many current models of agrammatic comprehension, we must first confront an epiphenomenon. Consider the following three facts:

1. In the world's languages, subjects typically precede objects.
2. Subjects are typically assigned thematic roles that are higher in thematic hierarchies than the thematic roles assigned to objects.

3. Agents (the do*ers* of an action) typically occur before Themes (the do*ees* of an action).

The canonical order of thematic roles is a statistical fact. It does not follow from any principle in linguistic theory. It is, that is to say, merely epiphenomenal, as far as linguistic theory is concerned. However, many models of agrammatic comprehension have been based squarely on the epiphenomenon of linearity, among them, Avrutin (2006), Caplan and Futter (1986), Linebarger (1995), and Piñango (2000). The guiding notion is that Broca's aphasics resort to a strategy in which thematic roles are assigned in a linear order. The Agent role, the highest role in all thematic hierarchies, is assigned to the first relevant noun phrase (NP) in a sentence. A role that is lower in a thematic hierarchy is assigned to a second relevant NP, and so on.

This reliance on linearity is true also of the trace-deletion hypothesis, henceforth TDH (Grodzinsky 1986, 2000).

The TDH invoked a concept from linguistic theory, the concept of syntactic movement and trace. In the 1980s, when the TDH was first formulated, very few researchers working with aphasic data were inclined to regard linguistic theory as relevant; so, viewed against that atheoretical background, the TDH, in opting to construct a hypothesis based on something theoretical, amounted to a trail-blazing proposal.

An early formulation of the TDH (Grodzinsky, 1986) proposed that in an otherwise normal representation, traces in theta positions (i.e., positions to which thematic roles such as Agent or Theme are assigned) are deleted. Since the trace is lost, thematic role information is also lost in NPs that have undergone movement. Broca's aphasics are apparently unable to infer the missing role by consulting their knowledge of the roles that the relevant verb requires. Instead, and this is where the reliance on linearity asserts itself, they resort to a nonlinguistic default strategy which assigns a role to the moved NP according to its serial position in the surface string (e.g., in a sentence with two NPs, if the verb is *bite*, and if the first NP in the surface string is the one that has moved, the strategy assigns it the role of Agent; if the second NP in the surface string is the one that has moved, the strategy assigns it the role of Theme; and so forth).

How does this play out in a passive sentence such as (1) which many Broca's aphasics tend to guess at, when the task is sentence-picture matching? What happens in the unimpaired representation is that the NP argument of the *by*-phrase (*the baker*) receives the Agent theta role, but not via movement. The subject (*the zebra*), by contrast, is derived by movement, and so is linked to a trace. In (1), the normal role assignments are given:

(1) [The zebra]$_i$ was bitten t_i by [the baker]
THEME AGENT

Because no movement is involved in the assignment of the Agent role to *the baker*, it is not linked to a trace, and the prediction is that Broca's aphasics will have no difficulty with that assignment; they get it for free via the syntax, which is by hypothesis unimpaired except with respect to movement. The NP (*the zebra*) is derived by movement, but since the trace it is linked to is deleted in a Broca's representation, thematic role assignment cannot be accomplished syntactically. The parser outputs an incomplete representation and its job is done.

Enter the default strategy. It assigns the role of Agent to the moved NP. The result is that the Broca's aphasic has a representation of the passive that contains two Agents, as in (2), where '*' indicates loss of trace:

(2) [The zebra] was bitten* by [the baker]
AGENT AGENT
(via default) (via syntax)

When asked to complete a sentence-picture matching task, the representation in (2) compels Broca's aphasics to guess which NP to interpret as Agent. Thus, their performance is random. Consequently, in the passive, we see that random performance is accomplished by means of trace deletion, the application of a linear default heuristic, and the resulting competition for Agenthood.

How is the frequently observed above-chance performance on active sentences by Broca's aphasics explained? If, as in earlier versions of syntactic theory, it is assumed that there is no movement in sentences such as (3), then the representation of a Broca's aphasic is complete and thus there is no reason for the linear default strategy to be triggered.

(3) [The zebra] bit [the baker]
AGENT THEME
(via syntax) (via syntax)

Thus far, we have seen how the TDH explains the core findings that Broca's aphasics perform above chance on actives and randomly on passives. Now, we turn to the other core findings, above-chance performance on subject relatives in sentence-picture matching tasks, but random on object relatives. Let us see how the TDH accounts for these. With respect to object relatives, earlier versions of syntactic theory assumed only one movement, as in (4):

(4) Point to [the zebra]$_i$ Op$_i$ that [the baker] bit t_i
THEME AGENT

In (4), the movement of *the zebra* is from the object position, now occupied by the trace. In an aphasic representation, lacking trace, the default strategy assigns the Agent role to the first NP (*the zebra*), and normal assignment obtains for the subject, *the baker*, as in (5):

(5) Point to [the zebra] that [the baker] bit*
AGENT AGENT
(via default) (via syntax)

As in the passive, there are two Agents. The aphasic guesses and random performance follows.

In the subject relative, the normal representation is as follows:

(6) Point to [the zebra]$_i$ Op$_i$ that t_i bit [the baker]
AGENT THEME

In a Broca's representation, in which trace is lost, the Agent role is assigned to the NP (*the zebra*) by the default strategy,

which happens to be the correct assignment, compensating for the loss of trace, and yielding a normal interpretation:

(7) Point to [the zebra] that* bit [the baker]
AGENT THEME
(via default) (via syntax)

The above examples show how the TDH succeeded in partitioning the core data. At this point, note only that in the three examples in which a trace is involved, the application of the atheoretical default strategy is necessary for the data to be partitioned in the desired way. No default strategy, no division. The strategy is already doing much of the heavy lifting, but now we will see that it works overtime, changing freely, to keep pace with selected empirical anomalies and theoretical developments.

Here is an example of an empirical anomaly which prompted a change in the default strategy. A study by Hickok and Avrutin (1995, 1996) on *wh*-questions reported that Broca's aphasics performed above chance on *which-N* questions involving subject extraction, such as (8), but at chance on *which-N* questions involving object extraction, such as (9).

(8) [Which horse]$_i$ t_i kicked [the giraffe]
AGENT THEME

(9) [Which horse]$_i$ did [the giraffe] kick t_i
THEME AGENT

In (10), application of the default assigns the Agent role to *which horse*, and thus aphasics perform in a manner similar to normal subjects, above chance. In (11), the default assigns the Agent role to *which horse*, but now both NPs in the sentence have the Agent role. Forced to guess, random behavior is assured in Broca's aphasics.

(10) [Which horse]* kicked [the giraffe]
AGENT THEME
(via default) (via syntax)

(11) [Which horse] did [the giraffe] kick*
AGENT AGENT
(via default) (via syntax)

So far, so good. However, Hickok and Avrutin also reported above-chance performance for *both* subject- *and* object-extracted *who* questions, (12) and (13).

(12) [Who]$_i$ t_i chased [the horse]
AGENT THEME

(13) [Who]$_i$ did [the horse] chase t_i
THEME AGENT

The problem is with (13). According to the TDH, the default should assign the Agent role to the moved wh-phrase, but this would mean that both NPs are Agents, and therefore subjects should behave randomly, contrary to fact:

(14) [Who] did [the horse] chase*
AGENT AGENT
(via default) (via syntax)

Hickok and Avrutin (1995, 1996) account for the differences in *who* questions and *which-N* questions by appealing to Cinque's (1990) distinction. He proposed that *which-N* phrases are referential and yield one kind of chain, a binding chain, whereas *who* phrases are nonreferential and yield a different kind of chain, a government chain. So, there is a theoretical distinction between the two kinds of questions, consistent with Hickok and Avrutin's data; but inconsistent with the TDH.

To address the problem, Grodzinsky (1995, p. 46) elected to revise the strategy (which, being atheoretical, can change without constraint) by asserting that the default strategy applies only to referential NPs. Since it could be argued that *who* is nonreferential, the TDH does not apply.

Another theoretical development was about to test the flexibility of the default strategy like never before: the VP-internal subject hypothesis, henceforth VPI.

A consensus had formed that subjects are base generated within VP and undergo movement. An immediate consequence is that traces occur in virtually every sentence, including simple actives. Apply this to the TDH and traces are deleted in virtually every sentence Broca's aphasics hear. And yet, Broca's aphasics do not have problems understanding virtually every sentence they hear, so trace-deletion per se makes no predictions at all. More and more obviously, what plays the crucial role in distinguishing sentences Broca's aphasics understand from those they do not is the theory-free default strategy. In fact, only by virtue of the strategy does the TDH have any consequences.

The VPI not only exacerbated the conceptual difficulties faced by the TDH, but it multiplied its empirical problems exponentially, as we will now see. In a single-clause sentence with a transitive verb such as *chase* and two referential NPs {Agent; Theme}, the three logical possibilities for linear role assignment are as follows:

Option A	NP1 moved Agent assigned by default	NP2 not moved Correct role assigned normally
Option B	NP1 not moved Correct role assigned syntactically	NP2 moved Theme assigned by default
Option C	NP1 moved Agent assigned by default	NP2 moved Theme assigned by default

Instances of Option A are easy to find. One such example is the passive sentence in (2) above, repeated for convenience as (15):

NP1 moved NP2 not moved
(15) [The zebra] was chased* by [the baker]
AGENT AGENT
(via default) (via syntax)

An example of Option B is not so easy to find, but for Option C, there are examples in abundance, especially from languages in which word order is freer than it is in English. Even with the English sentences above, the TDH unravels. Consider the object relative clause in (4) and (5). There was

only one movement prior to VPI, but now there are two, as shown in (16):

(16) Point to [the zebra]$_i$ Op$_i$ that [the baker] t$_j$ chased t$_i$
THEME AGENT

The core finding is that Broca's aphasics perform randomly on such sentences. When there was only one movement, the TDH could account for the data, as shown in (4) and (5). Now that there are considered to be two movements that result in two NPs that do not receive theta roles syntactically, but must acquire them both via the default strategy, what does the TDH predict? Application of the default strategy in a linear fashion to both NPs must give the following aphasic representation, as indicated in Option C above:

NP1 moved NP2 moved
(17) Point to [the zebra] that [the baker]* chased*
AGENT THEME
(via default) (via default)

In (17), since the TDH default strategy assigns roles by linear positions, the Agent role is assigned to the first NP (*the zebra*) and the Theme role to the second NP (*the baker*). Thus, subjects would be predicted to perform reliably *below chance*, as their role assignment is exactly the opposite of the unimpaired subject's role assignment (16). Since Broca's aphasics in fact perform at chance, this prediction is wrong.

The TDH now also makes the wrong prediction with the *which-N* question in (9), *Which zebra did the baker chase*. Prior to ISH, the TDH could arrive at the chance (random) prediction that is consistent with fact, but now that the subject NP (*the giraffe*) moves in addition to the wh-phrase, it would yield a below-chance prediction, contrary to fact, as shown in (18):

(18) [Which zebra] did [the baker]* chase*
AGENT THEME
(via default) (via default)

In (18), once again, since the TDH default strategy assigns roles by linear positions, the Agent role is assigned to the first NP (*which zebra*) and the Theme role to the second NP (*the baker*). Thus, subjects would be predicted to perform reliably *below chance* (their role assignment is exactly the opposite of the unimpaired subject's role assignment).

Another problem, for the end is not yet: The combination of VPI and the default strategy predicts anomalous results with any sentence type which does not assign an Agent role and which only involves a single dependency. In this respect, adjectival passives are of interest. Adjectival passives are derived in the lexicon, unlike verbal passives, which involve syntactic movement from object position (Levin and Rappaport, 1986). An example of the structure of an adjectival passive is given in (19). The negative prefix *un-*, which only attaches to adjectives, is often used as a test of an adjectival passive.

(19) The man$_i$ [was [$_{AP}$ t$_i$ unhurt] in the accident]

Because it is lexically derived, the adjectival passive has a structure involving a predicate-internal trace, as can be seen in (19). What is interesting here, however, is that adjectival passives assign a Theme role to their predicate-internal position.

With that in mind, consider the finding by Grodzinsky et al. (1991) that Broca's aphasics performed above chance on adjectival passives involving negative *un*-prefixation. In this study, the VPI was not assumed, and above-chance performance was predicted because no trace was thought to be involved. However, as we see in (19), adjectival passives with negative un-prefixation *do* involve movement and contain a trace. Application of the default strategy would assign the role of Agent, not Theme, to the moved subject of an adjectival un-passive, and therefore comprehension should be seriously impaired, which it is not.

The problems posed by the VPI with English sentences is challenging enough, but once we look at Broca's aphasia in languages with less restrictive word order than English, the problems mount up exponentially for the TDH and its linear strategy. We will consider only two examples here, but see Beretta (2001) for other examples.

Japanese scrambled actives (in which the object NP moves to the front), such as (20) yielded chance performance by Broca's aphasics in a study by Hagiwara and Caplan (1990).

(20) Hanako$_i$-o Taro$_k$-ga t$_k$ t$_i$ nagutta
Hanako-Acc Taro-Nom hit
'Taro hit Hanoko'

According the TDH, however, the prediction is for below-chance performance:

(21) [Hanoko]-o[Taro]-ga**nagutta
AGENT THEME
(via default)(via default)

In Korean actives (22), in which the object NP is dislocated to a sentence-initial position, Broca's aphasics perform at chance (Beretta et al., 2001).

(22) saja-lul$_i$ key-ka$_j$ t$_j$ t$_i$ mul-eyo
lion-Acc dog-Nom bite-COMP
'The dog bit the lion'

As with the Japanese case, the TDH wrongly predicts below-chance performance, as in (23):

(23) [saja]-lul [key]-ka** mul-eyo
AGENT THEME
(via default) (via default)

There are many other crosslinguistic data one could discuss here, but the moral of the story is by now abundantly clear. With the VPI and frequently *two* dependencies for the default strategy to deal with, data from languages with relatively free word order were always going to raise difficulties for the TDH and its commitment to a linear heuristic to do the work of partitioning data, and so it proved.

The TDH solution to the two-dependency problem posed by the VPI was to simply add another strategy. This new strategy, called *theta-bridging* (Grodzinsky, 2006), in effect absolves Broca's aphasics of any constraints imposed by the linguistic theory, in this case, the VPI. By stipulation, they do not have to attend to the dependency involved in subject movement out of VP.

But by now, we are very far indeed from any commitment to theoretical relevance.

What Challenges Lie Ahead?

If we can agree that the ultimate goal of neurolinguistic inquiry is theory unification, then muzzling linguistic theory by shackling it to a theory-free strategy is inimical to that goal. The linear models do not entirely dismiss linguistic theory, but they have set out their stall in such a way that they fail to make a single prediction without the effective agency of a linear strategy. The strategy, in all of the linear models, is designed to compete with syntactic processes in the sentences Broca's aphasics do not understand, but not to compete in those they do understand. However, nothing constraints strategies, and linearity of role assignment does not follow from anything in linguistic theory. And, absent a linear *deus ex machina*, there is simply no way that the linear accounts can divide the Broca's comprehension data in the required manner.

Linearity, we must conclude, is not a useful concept to invoke in inquiry into aphasic comprehension deficits, either empirically or conceptually. But independently of the arguments and evidence above that lead to this conclusion, there is another line of reasoning that lends support to it: relating language disorders to processing in the normal, unimpaired population.

Many commentators have observed that Broca's aphasics retain much, conceivably all, of their syntactic knowledge. After all, it has been reported that they can understand not just simple actives, subject relatives, but also clitic-doubling actives, subject clefts, raising constructions, and adjectival passives, among many other constructions (e.g., Avrutin, 2006; Beretta et al., 1999, 2001; Grodzinsky et al., 1991). If structural knowledge is more or less intact in these cases, then surely structure-building processes are also largely preserved in Broca's comprehension. After all, it would be entirely implausible that Broca's aphasics could understand all of the structures that they do if they did not possess extensive resources for structural analysis. Assuming that they do in fact have such resources, we are confronted with the question as to where these resources come from. Parsimony suggests that they were always there, but now perhaps restricted following neural insult. If we wish to press this view into service, then we have no choice but to commit ourselves to grounding our approach to Broca's comprehension in relation to a model of normal comprehension.

Linear models are not sympathetic to this view. As Friederici and Gorrell have pointed out, the TDH "lacks any connection to theories of sentence comprehension in normals" (1998, p. 260), a point also made with some force by Mauner (1995, p. 364). There seems to be little motivation to propose and defend extralinguistic models of linear heuristics in the absence of any evidence that Broca's aphasics resort to processes that are unlike those used by the normal, unimpaired population.

In this connection, Lukatela et al. (1991) have proposed that we would do better to relate aphasic deficits to the normal case. They reported that both Broca's aphasics and Wernicke's aphasics exhibit an identical pattern of comprehension errors in relative clauses in Serbo-Croatian, and furthermore, they are both different from controls only in the quantity of errors they make, but not in the kind of errors they make. In a similar vein, considering experimental reports in language development, dyslexia, aphasia, and normal adults sentence processing, Crain et al. (2001, p. 294) conclude that, "the results of experimental investigations across several subject populations reveal parallel patterns of linguistic behavior on [relative clauses]". Crain et al. believe that a processing account that encompasses both disordered and normal sentence processing would do justice to the facts. Caplan and Waters (1999), considering the role of memory in sentence processing, observe that in "many experimental paradigms, the processing of syntactically more complex sentences is not disproportionately affected by a concurrent verbal memory load, either in normal subjects or in subjects with extremely reduced working memory capacity or in aphasic patients" (p. 92).

If we are to meet the challenge of relating disordered language processing to normal language processing, it will entail a more concerted effort to carry out online rather than offline studies. In an excellent review of real-time comprehension in agrammatic aphasia, Schumacher (2009) presents a compelling case for using online techniques. There has been a steady tradition of this approach in studies of agrammatism (e.g., Blumstein et al., 1998; Burkhardt et al., 2008; Haarman and Kolk, 1994; Love et al., 2008; Prather et al., 1997), though these are more the exception than the rule.

To conclude, in order to rescue many current models from a parochial dependence on atheoretical concepts, the major challenge that lies ahead is to view agrammatic comprehension as complementary to normal processing, and to pursue online inquiry rather than offline. There are already efforts in that direction and it would be surprising if this were not to become the norm.

Abstract

This article describes the undertaking of linguistic fieldwork, in which linguists study languages as they are spoken in a naturally occurring domain, rather than in a laboratory or via self-introspection. This article presents the history of linguistic fieldwork, the rise of language documentation as a major paradigm for fieldwork, fieldwork research methods, ethics and community relations, and data management issues.

What Is Linguistic Fieldwork?

The traditional understanding of *linguistic fieldwork* involves a trained linguistic scientist traveling to a remote location to live in a speech community in order to study, describe, and theorize about that community's language or the human language capacity in general. In describing the nature of prototypical fieldwork, Hyman (2001) lists three features that linguistic fieldwork exhibits. The first of these is *distance*, meaning that the research usually takes place at some distance from one's home ("That is, 'fieldwork on Kikuyu' on one's vitae becomes synonymous with 'I did fieldwork on Kikuyu in Kenya'" (Hyman, 2001, p. 16)). The second of these is *exoticism*, meaning that the language under study is usually a minority language, an understudied language, an endangered language, etc. Hyman's third characteristic of prototypical fieldwork is *duration*, meaning that the research must take place over an extended period of time, with a commitment to spending many months in the field and years investigating the language.

While these traditional characteristics of fieldwork are considered by some to be the hallmarks of true linguistic fieldwork (e.g., Crowley, 2007; Samarin, 1967), in the last decade other less-prototypical scenarios are becoming increasingly accepted and even encouraged as valid examples of linguistic fieldwork. For example, fieldwork may take place in a speech community that is living in a diaspora situation away from its homeland, perhaps in a large urban setting like New York City or London. Fieldwork may also take place in a culturally defined subcommunity of the majority language community; for example, Eckert's (1989, 2000) and Bucholtz's (2011) work on language use among American high school students. Fieldwork may even be considered to start in the college classroom in a linguistics field methods course or by working with a lone individual, although these scenarios usually lead to the more traditional model of time spent in-community by the researcher later, in order to observe the language in use in a naturalistic setting.

What all these definitions have in common is that in fieldwork, the linguist attempts to study a language by observing it in one or more of its naturally occurring domains of use. While the notion of a *domain of use* can vary from a remote village where the language has been spoken for generations, to an urban marketplace, to a religious ceremony, to a staged conversation between two fluent speakers who are far from the home community, fieldwork is distinct from other linguistic research methods in that it strives to collect data by working with people who speak the language under study (as opposed to, say, introspective or corpus-based methods).

The products or outcomes expected from linguistic fieldwork are also changing. Previously the expected products of fieldwork were limited to those that primarily served linguistic science, whether descriptive (i.e., the so-called 'Boasian trilogy' of a dictionary, a descriptive grammar, and a collection of texts) or theoretical (examples from an 'exotic' language to prove or disprove theories) in aim. Today, however, the products of fieldwork can reach a much broader audience. The focus since Hale et al. (1992) on the endangered language crisis has led to an increase in the production of language teaching materials and revitalization programs as a goal of fieldwork, as well as increased attention to capacity building activities in language communities. The emerging discipline of language documentation, described below (and see, e.g., Gippert et al., 2006; Himmelmann, 1998, 2012; Grenoble and Furbee, 2010; Woodbury, 2011), has also led to the production of annotated digital media corpora consisting of audio and video recordings of language in use, along with time-aligned transcription, translation, and analysis as a central goal of linguistic fieldwork. These documentary corpora are intended to serve as wide an audience as possible, including linguists, language communities, teachers, and others.

Furthermore, the notion of who is a fieldworker is changing. Traditionally, linguistic fieldworkers have been professional linguists, graduate students, or Christian missionaries studying a language in order to facilitate Bible translation. Now, however, it is common to find members of the speech community themselves doing fieldwork; these people may or may not be trained in linguistic science, and may be teachers, clergy, or interested laypersons with a personal stake in the study of their native or heritage language.

In fact, the term *fieldwork* has recently come under scrutiny. This is because for many people who undertake the study of language *in situ*, the traditional notion of 'going to the field' does not hold – these people are often working in their home communities, with relatives or friends serving as language consultants. However, this article continues to use the term *fieldwork* as it is used in the sciences, to distinguish the study of language in its natural environment from that in

a laboratory setting; the terms *fieldworker* and *field linguist* here are used to indicate the person who undertakes such activities, whether or not that person is affiliated with an academic institution.

History of Linguistic Fieldwork

The history of linguistic fieldwork, broadly defined, goes back at least five centuries, when Spanish and Portuguese colonists in Africa, Asia, and the Americas embarked on the study of indigenous languages in the service of exploration and Christian mission work. Philologically grounded interest in the collection of wordlists was also popular in eighteenth- and nineteenth-century Europe among scholars and laypersons alike; see Chelliah and De Reuse (2010) for a full account of the early history of linguistic fieldwork.

Contemporary fieldwork is generally considered to have started with Franz Boas in the late nineteenth and early twentieth centuries (see Rosenblum and Berez, 2010; Sakel and Everett, 2012; Woodbury, 2011). In his anthropological work in indigenous communities along the Pacific Northwest coast of North America, Boas stressed the importance of language as an inextricable component of ethnological studies as a whole. He advocated the collection of texts, especially those written by native speakers, as part of the complete description of a language. This was a sharp turn from previous linguistic fieldwork, which focused on the production of generalizing descriptive grammars and dictionaries or wordlists as the essential products of fieldwork. Boas also became the progenitor of a tradition of American fieldwork-based linguistic inquiry via his arguably most-notable student Edward Sapir, who trained, among others, Mary Haas and Morris Swadesh. Haas then went on to train at least 50 graduate students in linguistic fieldwork through her position at the University of California, Berkeley, and the Survey of California and Other Indian Languages (Turner, 1997).

Turning to other regions, the history of fieldwork on the Aboriginal languages of Australia, summarized in McGregor (2008), can roughly be divided into three periods: an early period from the 1770s until about the 1930s that was marked by the collection of wordlists and a few descriptive grammars by amateurs; a middle period from approximately the mid-1930s until the 1960s, in which professional linguists conducted fieldwork, equipped with new ideas and institutional backing; and a late period from the 1960s to the present, in which the presence of missionary linguists and Aboriginal involvement in fieldwork has expanded rapidly (see Blake, 1981; Capell, 1970; Dixon, 1980; Dixon and Blake, 1979; McGregor, 2004; O'Grady et al., 1966; Wurm, 1972 for more details).

Furthermore, fieldwork in the Pacific region – and especially on languages of the Austronesian family – was facilitated during the second half of the twentieth century in large part by linguists working at the University of Hawai'i at Mānoa. There, the Pacific Lexicography Center and, later, the Pacific and Asian Linguistics Institute, supported fieldwork in languages of Micronesia, Polynesia, and the Philippines (Grace, unpublished).

During the rise of generative linguistics in America in the second half of the twentieth century, fieldwork, while still a popular research methodology in Australia and the Pacific, fell out of favor in the United States (with the exception of research on languages of the Americas as part of the Boasian tradition described above). As Chelliah and De Reuse (2010) note:

> The Chomskyan program saw the biological unity of a language learning device and a universal grammar underlying that device. Since the grammar of all languages was presumed to be the same, the study of exotic unwritten languages was not seen as necessary and it was thought that the goals of understanding universal grammar could just as well be accomplished by studying well-known languages. Another advantage of using well-known languages was that speakers were readily available and easily trained in providing grammaticality judgments or introspective comments on a language.
>
> Chelliah and De Reuse, 2010, pp. 60–61

The Rise of Language Documentation as a Paradigm for Fieldwork

However, since the early 1990s, attention has once again turned to the value of linguistic fieldwork, spurred in particular by the crisis of language endangerment and extinction (e.g., Austin and Sallabank, 2011; Evans, 2009; Grenoble and Whaley, 1998; Hale et al., 1992; Harrison, 2007; Nettle and Romaine, 2000). Krauss's (in Hale et al., 1992) admonition that linguists not let the discipline "go down in history as the only science that presided obliviously over the disappearance of 90% of the very field to which it is dedicated" (Krauss in Hale et al., 1992, p. 10) has given rise to a new paradigm of linguistic fieldwork called alternately *language documentation* or *documentary linguistics*. (Some suggest that the term *documentary linguistics* situates this new paradigm as a subfield of linguistics (like *sociolinguistics* or *historical linguistics*), while *language documentation* remains agnostic or relegates it to an applied status. Except in direct quotes, for this article I use *language documentation* because it has become the more widely used of the two terms, although I still maintain that the practice is as worthy of theorization as any other subfield of linguistics (cf Woodbury, 2011).)

Himmelmann (1998) distinguishes the *documentation* of languages from the *description* of languages, both of which arise from fieldwork:

> Much of the work that is labeled 'descriptive' within linguistics comprises two activities, the collection of primary data and a (low-level) analysis of these data. These are indeed two separate activities as shown by the fact that the methods employed in each activity differ substantially. To date, the field concerned with the first activity – called 'documentary linguistics' here – has received very little attention from linguists. [I propose] that documentary linguistics be conceived of as a fairly independent field of linguistic inquiry and practice that is no longer linked exclusively to the descriptive framework.
>
> Himmelmann, 1998, p. 161

The rise of language documentation has had a tremendous affect on linguistic fieldwork in the last two decades. Funding agencies have arisen exclusively to fund fieldwork projects

that are documentary in nature (e.g., The Hans Rausing Endangered Language Documentation Programme, the Dokumentation Bedrohter Sprachen of the VolkswagenStiftung, the National Science Foundation/National Endowment for the Humanities Documenting Endangered Languages Program, the Foundation for Endangered Languages, and the Endangered Language Fund). Fieldwork textbooks now discuss documentation methodology (e.g., Bowern, 2008), and academic programs to grant postgraduate degrees in language documentation have been developed (e.g., in the Department of Linguistics at the University of Hawai'i at Mānoa and the Endangered Language Academic Programme at the School of Oriental and African Studies of the University of London). Major research initiatives have explored the infrastructure needed to support language documentation (e.g., The Electronic Metastructure for Endangered Languages Data project (EMELD); inNET). Several edited volumes on documentation and documentary fieldwork (e.g., Gippert et al., 2006; Grenoble and Furbee, 2010; Thieberger, 2012) as well as journals and series (*Language Documentation & Conservation*, *Language Documentation and Description*) have been published.

Summarily, the goals of language documentation fieldwork include the creation of a corpus of audio and video records of observable linguistic behavior, the annotation of those records with enough translation, analysis, and metadata that the records will be useful and accessible to a wide audience, and the responsible preservation and dissemination of those records and annotations (see, e.g., Himmelmann, 1998, 2006; Woodbury, 2011 for discussion). Documentation also goes hand in hand with the field of language revitalization, maintenance, and conservation.

Fieldwork Research Methods and Activities

A great deal of work goes into preparing for fieldwork. These include selecting the language of study, finding an appropriate fieldsite, developing a research agenda, getting visas, finding funding, purchasing equipment, and learning as much as possible about the language, culture, and field site.

Once in the field, fieldworkers typically think of their work as occurring in *sessions*, usually 1–3 h of time spent working with one or more speakers of the language (these speakers are usually called *consultants*, *informants*, *teachers*, *assistants*, etc.). A typical day of fieldwork will consist of one or two sessions, plus preparation time before each session and processing time after each session. A range of activities can take place during a session: *elicitation* of lexical, grammatical, and metalinguistic knowledge; *recording* examples of language in use; and *transcription and translation* of those recordings. In reality the division between these activities is not so clearly defined. For example, during transcription and translation work the linguist and consultant may break away to investigate an interesting grammatical phenomenon or to collect lexical data from a particular semantic field.

Elicitation is the direct questioning of the consultant(s) about a particular aspect of the language. Usually elicitation of lexical items (vocabulary) is the first kind of work to take place between a researcher and a consultant; the researcher will ask the consultant for words of simple nouns like body parts and use this information to understand the phonology of the language in question (see Bowern, 2008 for advice on initial phonetic/phonological fieldwork; Ladefoged, 2003 for advanced instrumental fieldwork on phonetics). Lexical elicitation can also be a part of more advanced fieldwork, in service of producing dictionaries (Frawley et al., 2002; Mosel, 2004; Nichols and Sprouse, 2003). Elicitation can also be used to investigate other parts of grammar, including morphology and syntax. The linguist may ask the consultant 'how do you say X in your language?' or she may provide a scenario and ask the consultant how that scenario is usually expressed in the language ('if you were thirsty, how would you ask for something to drink?'). In some cases the linguist may provide constructions in the language and ask the consultant to explain the difference, or the linguist may ask whether a certain construction is grammatical or not. Some consultants can quickly become adept at providing paradigms. Elicitation can also be aided with the use of short video clips of actions or states as stimulus, like those provided online by the Language and Cognition Group at the Max Planck Institute for Psycholinguistics in Nijmegen.

Elicitation, while a useful method for investigating some aspects of language, requires the consultant to reflect consciously on his or her knowledge of the language. This is cognitively a different kind of linguistic behavior from using language for communication, and thus it is unwise for linguists to base their research solely on elicitation. It is very important to also include the *recording of examples of language in use* in a range of genres and modalities – indeed these kinds of data make up the bulk of a language documentation corpus. Examples of language in use include nearly any kind of running speech like narration, conversation, instructional discourse, oration, etc. These kinds of language use may be more or less spontaneous (see Himmelmann, 1998) and may be either staged for the researcher or naturally occurring.

Staged or controlled speech events for recording may include asking a consultant to tell a traditional story in the language, or asking a consultant to talk about a personal experience, either of her own choosing or in response to a question like 'have you ever been in mortal danger?' or 'tell me about your first day of school.' Visual stimuli may also be used; entire research paradigms have grown out of the use of the 'pear film' (Chafe, 1980) and the 'frog story' (Strömqvist and Verhoeven, 2004) in fieldwork. (The 'pear film' is a wordless video about a pear farmer, and a boy, and a bicycle, while the 'frog story' is a wordless picture book about a boy, a dog, and a frog (Meyer, 1969). In these research paradigms, consultants are asked to narrate these in their language.) Conversational speech events may also be somewhat staged by providing consultants with a topic for discussion; Bowern (2008, p. 123) suggests games like 'what am I thinking of?' and giving directions. Naturally occurring speech events are also potentially recordable and should be included in a well-rounded corpus. These include public events like ceremonies, performances, lectures, radio programs and the like, as well as conversations among consenting participants (not necessarily in the presence of the linguist).

Recordings of language are of little use if they are not accessible to people who do not speak the language, and therefore transcription and translation are key fieldwork activities.

Transcription is the writing (or typing) of the contents of the recording, usually either in the International Phonetic Alphabet or in a locally accepted orthography. Translation involves translating the transcription into another language (usually the language of wider communication and/or a major language like English), which can happen in units of various sizes. Transcriptions can be translated at the level of phrase or sentence (usually referred to as a *free translation*), at the word level, or at the morpheme level. In all cases, transcription and translation involve analysis, of phonology during transcription and of morphology, syntax, semantics, and discourse during translation.

If the field linguist is also a fluent speaker and writer of the language under study, transcription can be a fairly rapid process. However, if the field linguist is not a speaker of the language, then she must work with a consultant, who can repeat the words on the recording slowly and clearly to the linguist, who will write them down. Translation is also a time-consuming task, and the linguist should take care to avoid the range of pitfalls that come with translating between one language and another (Crowley, 2007; Gil, 2001).

Note that no single method is enough. Consultants who are skilled at metalinguistic activities may not be fluent enough or comfortable enough to provide running speech, and fluent speakers are not necessarily adept at introspection. Importantly, a phrase that sounds ungrammatical out of context may indeed be a licit part of a naturalistic speech event, and thus grammaticality judgments can be suspect. In reality, fieldwork involves all research methods described here happening simultaneously and circularly. As the field researcher learns more about the language, she may need to go back and re-elicit, retranslate, or reanalyze previous work.

Ethics and Linguist–Community Relations

As in medical and biological research, linguists are bound to practice ethical research methods during fieldwork. Ethics has been the subject of a great deal of discussion in the last few decades, with special attention to the notion of community collaboration (discussed below) in language documentation. Because they work with human subjects, most linguists are bound by university-based ethics panels, also referred to as Human Subject Committees or Internal Review Boards. Linguistic fieldwork projects must be approved or exempted by such a committee before the researcher can commence work.

However, given that linguistic fieldwork takes place in parts of the world that may be culturally quite diverse, most researchers agree that it is imperative to consider one's ethical responsibilities beyond what the university ethics panel has approved, since practices for, e.g., consent, may differ from those in the researcher's home country. The Linguistic Society of America has provided some guidelines for ethical field-based research:

- Linguists should do everything in their power to ensure that their research poses no threat to the well-being of research participants.
- Research participants have the right to control whether their actions are recorded in such a way that they can be connected with their personal identity. They also have the right to control who will have access to the resulting data, with full knowledge of the potential consequences.
- Linguists are responsible for obtaining the informed consent of those who provide them with data (regardless of whether and how that consent is documented), for maintaining any expected confidentiality in storing data and reporting findings, and for ensuring that any individual's participation in their research is completely voluntary at every stage. Anonymous observations of public behavior, which often cannot involve consent, should include no information that could inadvertently identify individuals or, where sensitive, the community.
- Linguists should carefully consider whether compensation of some kind is appropriate, be it remuneration for time and effort, or use of their knowledge and expertise to benefit participants or their communities.
- Where feasible, linguists should facilitate participants' access to their research results (Linguistic Society of America, 2009: pp. 2–3, reprinted in Rice, 2012, p. 410).

These guidelines are designed to protect the individual research participant while still being flexible enough to take cultural differences into account. In traditional social science research, anonymity of a participant is often an inviolable component of project design, but in some language communities, speakers may take pride in having their names associated with their utterances; the second bullet point above allows the speaker to make decisions with regard to his or her anonymity. Bullet point three requires that researchers ensure that participants consent to the research activity, but does not require a signature to that effect, since in many communities paperwork is regarded with suspicion (in such cases, verbal consent would be recorded). Bullet point four allows researchers and consultants to determine locally appropriate compensation, to avoid disrupting the local economy or causing offense (McLaughlin and Seydou Sall, 2001).

In addition to the ethical considerations between linguist and individual research participants, fieldwork also requires ethical consideration between the linguist and the speaker community. Although in many cases it is difficult to determine which individuals or bodies best represent the community, it is now well accepted that fieldworkers must strive to also take the needs, interests, and expertise of the speakers themselves into consideration when designing and conducting field-based projects.

In recent years the discussion about linguist–community relations in fieldwork and language documentation has tended to embrace a collaborative model (Cameron et al., 1992; Czaykowska-Higgins, 2009; Dorian, 2002; Dwyer, 2006; Gerdts, 1998; Grinevald, 1998, 2003; Hale, 2001; Hill, 2002; Penfield et al., 2008; Rice, 2006, 2011, 2012; Stebbins, 2003; Yamada, 2007), in which the linguist works cooperatively with the community to mutually meet the language goals of the researchers and the speakers simultaneously. At the very least, the linguist integrates into her research plans to return something of potential linguistic or educational value back to the community while also working toward her own research goals. For example, a field linguist writing a grammar may also use some of the information she collects to create language

teaching materials for teachers to use in local language maintenance programs, or she may install digital 'jukeboxes' of language recordings of traditional narratives on a computer in the local library for all to listen to. Other publications on collaborative research support a much more proactive and equitable relationship between the researcher and the community. Czaykowska-Higgins (2009), for example, extends the notion of *community-based research* (Cameron et al., 1992; Strand et al., 2003) to field linguistics, advocating research that is conducted *for, with, and by* community members. In this model, members of the speech community have an equal say in the design, implementation, and ownership of a fieldwork project:

> In its fullest form, Community-Based Language Research involves training members of the language-using community to do the research themselves, and can have as one of its goals the aim of making redundant the presence in the community of academic linguists who are not from the community.
>
> Czaykowska-Higgins, 2009, p. 25

Rice (2011) points out that in some parts of the world, communities already have guidelines for ethical research and/or research protocols in place to which outside field linguists must adhere. Canadian First Nations communities have been especially active in designing research protocols, see for example the discussion of the development of the Clearwater River Denesųłiné protocol in Cheecham and Wilhelm (2013) and the Gwich'in protocol for traditional knowledge research (Gwich'in Social and Cultural Institute, 2004). In the United States, the Alaska Native Knowledge Network provides guidelines for respecting cultural knowledge and strengthening indigenous languages when working with Alaska Native language communities (Alaska Native Knowledge Network, 2000, 2001).

The discussion on ethics and linguist–community relations has also recently included viewpoints that are distinct from the collaborative research model. Most notably are Dobrin (2008) and Holton (2009), who point out that while collaboration toward linguistic goals is laudable in places like North America, Australia, and New Zealand, in other parts of the world like Melanesia and Indonesia, there are other standards for ethical behavior by outsiders. Communities may have nonlinguistic goals for their relationships with field linguists. Dobrin describes experiences with fieldwork in Papua New Guinea, where having a positive relationship with an outside researcher was perhaps more important than actual language survival, and where 'the right to language choice includes the right to choose against language' (Dobrin, 2008, p. 300). In the case of Holton (2009), differing expectations for his role as patron as well as linguist led to awkwardness in his relations with a speech community in eastern Indonesia.

Finally, there is an ethical concern for the long-term care of the data collected during fieldwork. Especially when so many of the world languages, and the knowledge systems encoded within them, are endangered, fieldworkers have a responsibility to make recordings that are of the highest possible quality, to describe languages accurately, to ensure the longevity of the data collected, and to disseminate them responsibly. *Responsibly* in this case means finding a balance between the desires of the speakers for privacy and ownership of languages and recordings, and the need to manage one's data according to accepted best practices for fieldwork data sustainability. These best practices are discussed in the next section.

Data Management, Technology, and Archiving in Fieldwork

In their 2003 article, Bird and Simons brought to the forefront of the discipline of linguistics the importance of fully exploiting technology to create documentations of language that are long-lasting and multipurposeable. As field linguists increasingly took advantage of new technologies for capturing, storing, and disseminating language data, "new digital language resources of all kinds – lexicons, interlinear texts, grammars, language maps, field notes, recordings – [were] proving difficult to reuse and less portable than the conventional printed resources they replace" (Bird and Simons, 2003, p. 557). Since then, a great deal of research on digital processes, software, and infrastructure for linguistic fieldwork has taken place (e.g., EMELD, inNet). Technology and data management are primary concerns for the field linguist, who is responsible for not only documenting language but also seeing to the longevity and appropriate dissemination of the data.

The result is that field linguists must plan for and incorporate robust data management tasks into their fieldwork plans, and they must attend to these tasks both in the field while collecting data, and out, when undertaking postfieldwork processing. First, the linguist must plan for good-quality audio and video recording, including becoming familiar with the latest digital recording devices and microphones, understanding digital file formats like WAV and MP3, and learning how to arrange a recording environment for optimal sound or video quality with no background noises, disruptive light sources, etc. (see Margetts and Margetts, 2012).

The field linguist must also have a consistent plan for file management and metadata collection. File management tasks include selecting an appropriate file naming convention that gives each file a unique identifier, and developing a strategy for backing up files in the field. This may be especially challenging in field locations where electricity or dry storage conditions are in short supply. Metadata, which is key information about each file (e.g., date, language, location, demographic information about the people on the recording, etc.), must also be diligently collected (see Thieberger and Berez, 2012 for advice on data management in fieldwork).

The field linguist must also learn how to use and evaluate different pieces of software that she might use during data processing. For example, two of the most common software tasks for field linguistics are (1) time-aligning transcriptions and translation to audio and/or video, and (2) developing a lexical database. (*Time alignment* is the linking of bits of text (here, transcriptions and translations, but also possibly glosses, comments, notation of gesture, etc.) to the time code of a particular event in a piece of media. In many cases this is done by (a) referencing the media file and (b) referencing the

start and end times of, say, particular utterances within a marked-up text document of a transcription of that media file. See Berez (2007) and Thieberger and Berez (2012).) and (2) developing a lexical database. Before selecting software, field linguists must determine whether the output of the software is in an interoperable, human- and machine-readable format like XML, lest data eventually become inaccessible in the future, if the developer ever stops supporting the software. (Fortunately, there are already prominent pieces of software available for these linguistic tasks that field linguists use quite a bit: ELAN for time alignment of text to media and Fieldworks Language Explorer (FLEx) for building lexical databases and interlinearizing texts.)

A typical workflow for processing data collected during linguistic fieldwork is as follows. After the initial planning phases (which include determining a file name convention; coming up with a plan for backing up data in the field; and finding an archive to work with (more on this last below)), the fieldworker will make recordings during a session and also immediately collect metadata for that session. Audio and video data must then be transcribed, translated, and interlinearized, and lexical items must be entered into a lexical database. These items can then be used for analysis and in printed, online, and teaching materials, etc.

At each stage of the process – that is, after making recordings, after translating them, and after analyzing them – data should be regularly deposited in an archive. Field linguists should find a dedicated repository to work with before they leave for fieldwork, because the archive staff can make recommendations for proper depositing procedures. Many field linguists now make deposits via post directly from the field, or immediately upon returning home. There are a number of accepted digital language archives in the world, like those listed with the Open Languages Archive Community. Note that not every website, hard drive, or computer counts as an acceptable archive, and care should be taken that materials are safeguarded in a repository whose staff is knowledgeable about archiving language materials. Materials that are deemed private can be embargoed for a determined period of time, or access to materials can be made open to the public or restricted to a particular group of people (like members of the speech community).

Linguistic Presupposition

Rob A van der Sandt, University of Nijmegen, Nijmegen, The Netherlands

Abstract

Presuppositional information is encoded in linguistic expressions by means of so-called presupposition triggers or presupposition inducers. These items are linguistic means that signal that certain information is taken for granted in the linguistic or nonlinguistic context. One task for presupposition theory is to identify these triggers, explain what type of information they induce, and why they do so. A second task is to explain why and under what circumstances the information thus induced is preserved as an intuitive inference of the inducing sentence. The latter problem is the projection problem for presuppositions. Theories of presupposition can be divided into the following main classes: semantic, pragmatic, and dynamic theories. Semantic theories explain presupposition as a semantic relation between sentences. Pragmatic theories take the information a speaker takes for granted in making an assertion as their starting point. Dynamic theories locate sentence meaning in its context-change potential: presuppositional information should be part of input context as a precondition for contextual update. The two major variants are the satisfaction account and the anaphoric account. The former construes presuppositions as definedness conditions on input contexts. According to the anaphoric account presuppositional expressions are anaphors that should be bound to a contextually given antecedent.

Presuppositional information is information that is taken for granted by the participants in a discourse or a conversation. As such it has a different status from information the participants present as new or relevant. The latter information is said to be asserted. This distinction between presupposition and assertion is reflected in the linguistic structure of sentences. For example, by his use [1] a speaker typically indicates that he takes for granted that Adam ate the apple, and asserts that Thomas regrets that.

Thomas regrets that Adam ate the apple. [1]

The information that Adam ate the apple is called a presupposition of [1]. This presupposition is said to be linguistically induced by the use of the factive verb 'regret.'

This way of introducing the notion of presupposition calls for a distinction. And the basic distinction that should be made is the distinction between presupposition as information taken for granted and presupposition as induced, invoked, or triggered by a linguistic expression. The first notion is the notion of presupposition as background information, which is already given or taken for granted in a conversation. Stalnaker and Karttunen call it the common ground. The second notion is the notion of presupposition as information that is conventionally associated with linguistic expressions or syntactic constructions. It is found in the literature under a variety of names, potential or presupposition (Gazdar, 1979), conventional implicature (Karttunen and Peters, 1979), or elementary presuppositions (van der Sandt, 1988). Though the two notions of presupposition are fundamentally different there is a straightforward connection. If a linguistic element induces a presupposition, the sentence containing the inducing element will typically be appropriate in a context, which already contains the presuppositional information. Thus [1] will normally be judged appropriate in a context in which the information that Adam ate the apple is somehow established or taken for granted. If not, one should rather convey this information in an assertoric way as in [2].

Adam ate the apple and Thomas regrets that. [2]

Linguistic Encoding of Presuppositions

Linguistic presuppositions can thus be seen as pieces of information triggered or induced by certain linguistic structures. Such triggers can be identified by using specific tests. These tests rely on the fact that presuppositional information tends to escape from environments, which block ordinary entailments. The traditional test is constancy under negation. Other tests are embedding under epistemic modals, embedding in the antecedent of a conditional construction and questioning. Of these the negation test is the least reliable since negative sentences can, in many cases, be interpreted in a metalinguistic way so as to defeat the presuppositional inference (*see* Negation, Linguistics of).

Applying these tests to the verb *stop* identifies it as a presupposition inducer.

Hubert stopped smoking (at t). [3]
Hubert used to smoke (during some period preceding t). [4a]
Hubert did not smoke (after t). [4b]
Hubert did not stop smoking. [5a]
It is possible that Hubert stopped smoking. [5b]
If Hubert stopped smoking, he must be saving a lot of money. [5c]
Did Hubert stop smoking? [5d]

The presuppositional content of [3] is given in [4a], the nonpresuppositional content in [4b]. Only the presuppositional information is preserved as an inference from the embeddings in [5a]–[5d].

The following linguistic structures are widely recognized as presupposition inducers. The presuppositional information that is triggered by the relevant items is given in the b-sentences:

1. Definite Noun Phrases (definite descriptions often including proper names and indexicals; they induce a presupposition to the effect that there is some entity satisfying the description).

The King of France is bald. [6a]
There is a King of France. [6b]

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52036-4

2. Cleft constructions (including 'that-' and pseudoclefts; they trigger an existential presupposition that there is some entity satisfying the Verb Phrase).

It was Adam who ate the apple. [7a]
Someone ate the apple. [7b]

3. Focal stress (induces the same existential presupposition as clefts, though many authors want to account for this inference by an independent theory of focus).

Adam ate the apple. [8a]
Someone ate the apple. [8b]

4. 'Wh'-questions (the presuppositional material is obtained by existential quantification over the variable introduced by the 'wh'-expression).

Who ate the apple? [9a]
Someone ate the apple. [9b]

5. Quantifiers (the strong quantifiers 'all,' 'most,'…); weak quantifiers like 'some' are considered to be ambiguous between a presuppositional and a nonpresuppositional reading; the presupposition induced is that the domain of quantification is nonempty.

All of John's children are bald. [10a]
John has children. [10b]

6. Factive verbs ('realize,' 'discover,' 'regret,'…; they induce a presupposition that the presuppositional complement is true).

Thomas regrets that Adam ate the apple. [11a]
Adam ate the apple. [11b]

7. Temporal clauses ('before,' 'while,' 'since,' 'after,'…); as in [6] they induce information of a propositional nature.

After Adam ate the apple, he was expelled from Paradise. [12a]
Adam ate the apple. [12b]

8. Sortal restrictions on predicates ('bachelor,' 'close,'…; the presuppositional information consists of the requirement that the arguments of the predicate are of the appropriate sort).

John is a bachelor. [13a]
John is male, adult,…. [13b]

9. Implicative verbs ('manage,' 'succeed,'…; put a presuppositional requirement on the action denoted by the VP).

John managed to open the door. [14a]
It took some effort to open the door. [14b]

10. Verbs of transition ('start,' 'stop,' 'continue,'…; see [3] above).

The items from [1]–[4] are examples of existential presuppositions. They all involve an existential quantification over some individual or set variable. In [6] and [7] the presuppositional information is of a propositional nature. The items from [8]–[10] involve requirements on the applicability of a predicate. This is only a small sample of the linguistic structures that have been identified as presupposition inducing. Further examples include focus particles ('only' and 'even'), adverbs of repetition ('again,' 'too,' 'back'), but also, more controversially, counterfactual conditionals, nonrestrictive relative clauses, and discourse particles like 'because' and 'although.'

Projection

The presuppositions induced by simple sentences tend to survive under embedding, that is whenever a subsentence of a compound φ induces the presuppositional information χ this information will surface as an inference of φ. Karttunen (1973) was the first to note and catalog numerous exceptions to this generalization. Here are some examples. In the a-sentences the presupposition that John has children escapes from its embedded position, in the b-sentences the same presupposition does not surface as an intuitive inference.

If baldness is hereditary, John's children are bald. [15a]
If John has children, John's children are bald. [15b]
Either baldness is not hereditary, or John's children are bald. [16a]
Either John has no children or John's children are bald. [16b]
It is possible that baldness is hereditary and that John's children are bald. [17a]
It is possible that John has children and that John's children are bald. [17b]

In the terminology prevalent in the 1970s and 1980s, it is said that, in the a-sentences, the presupposition that John has children is projected to the main sentence, whereas it is said to be filtered or canceled in the corresponding b-sentences.

Semantic, Pragmatic, and Discourse Presupposition

We may distinguish between three main types of theories that deal with presupposition and projection: semantic, pragmatic, and discourse theories.

Semantic Theories

The semantic view originates in Frege and was revived by Strawson. It construes presupposition as a binary relation between sentences (or propositions). A presupposition is a requirement that has to be fulfilled for a sentence to have a truth value. Thus ψ is taken to be a presupposition of φ just in case ψ has to be true in order that φ has a truth value. This requires a semantics that allows truth-value gaps.

Assuming the standard definition of negation as an operator, which maps truth onto falsity and vice versa, semantic presupposition can then be defined as follows:

φ semantically presupposes χ if φ entails χ and not φ entails χ.

The defining characteristic is constancy under negation. The projection behavior of presuppositions in other embeddings follows from the definitions of the logical connectives and other operators. One problem for such theories is that they cannot handle the presuppositions triggered by adverbs like 'too' and 'even.' Here presupposition failure arguably does not affect the truth conditions of the sentence, but the appropriateness of the utterance. It also turns out that no definition of the logical connectives can be given which accounts for all the projection data. Defenders of the semantic account are thus forced to either postulate an ambiguity in the logical connectives or transfer the burden of explanation to pragmatics.

Pragmatic Accounts

Pragmatic accounts (*see* Pragmatics, Linguistic) view presupposition not as a semantic relation between sentences. Instead presupposition is viewed as a property of utterances. The basic notion is that of a speaker presupposing a proposition in a context of utterance. This allows for certain variability of presuppositions with the context of utterance. The first formally developed theory of this kind is found in Gazdar (1979). The basic idea here is that a presupposition of a sentence is preserved unless it conflicts with contextual information or with an implicature invoked by its utterance. In the case of [15]–[17] this amounts to the following. A typical utterance of one of the b-sentences will invoke the implicature that it is possible that John has no children. This implicature conflicts with the presuppositional assumption that he does and so the latter is canceled. Since no such implicature is invoked for the a-sentences, they will be interpreted as presupposition preserving.

Dynamic Theories

A different style of modeling is found in the dynamic approaches. The two main variants are the so-called satisfaction theory and the anaphoric or binding theory. The first derives from Stalnaker (1974) and Karttunen (1974) and has been developed in particular by Heim (1983) and Beaver. The anaphoric account is found in van der Sandt (1992) and Geurts (1999). Comparisons and different assessments of their relative merits are given in Beaver (1997) and Geurts (1999).

Both accounts start off from the idea that an utterance changes the context in which it is made. The basic requirement of the satisfaction account is that the presuppositional information should be entailed by the context of utterance. If so, the input context is incremented with the information contained in the inducing sentence. An utterance of [1] thus requires a context, which entails that Adam ate the apple. If this requirement is not met, the input context is not a suitable one. In this case a mechanism of accommodation is invoked. This means that the input context will (under appropriate conditions) be revised so as to incorporate the relevant presuppositional information thus restoring interpretability.

The anaphoric or binding account is formulated as an extension of discourse representation theory. The basic tenet is that presuppositions are anaphoric expressions (*see* Anaphora). Presuppositions only differ from pronouns and other attenuated anaphors in that they have internal structure and semantic content. The basic requirement is not that the presuppositional information is entailed by the context of utterance, but that the presuppositional anaphor should find a suitable antecedent. If no such antecedent is available, the semantic material carried by the presuppositional anaphor will be accommodated in the discourse structure so as to provide an antecedent after all.

The context-change semantics of the satisfaction theory generally yields weaker predictions than are found in the anaphoric account. This is due to the different status that presuppositional material has in both theories and to the different ways in which this material is processed. For example, for a conditional of the form $\varphi \rightarrow \chi_{<\psi>}$ where ψ is triggered by χ the satisfaction theory will predict $\varphi \rightarrow \psi$ as presupposition for the whole sentence. This yields for [15a] not the presupposition that John has children, but the presupposition that he has children *provided* that baldness is hereditary. Just like the classic semantic account, the satisfaction theory has thus to appeal to some pragmatic strengthening mechanism to derive the stronger presupposition that John has children. On the anaphoric account, presuppositional information is never transformed into a new semantic construct. Consider [15a] again. The presuppositional anaphor associated with the consequent cannot be bound to some preestablished antecedent. So some entity representing the set of John's children will be accommodated in the main context, thus yielding the stronger prediction that the utterance of [15a] presupposes that John has children.

Linguistic Synesthesia

Abstract

Congenital linguistic synesthesia involves aspects of language producing atypical automatic, involuntary, and consistently invariable sensory perceptions or associations, such as colors or flavors. While most commonly found with graphemes as the inducer and colors as the concurrent, other types involve phonemes and lexemes. Synesthesia differs from hallucinations or imagery in that the sensory perceptions are real and verifiable. Some forms of these neurological traits involve higher levels of myelination along unpruned neural pathways, producing atypical rates of feed-forward and feedback.

Definition

The word 'synesthesia' (British spelling, 'synaesthesia') comes directly from Greek συν- (syn-) 'union,' and αίσθησις (aisthesis) 'sensation,' thus meaning 'a union of the senses.' Synesthesia (pl. synesthesiae) is the general name for two complexes of over 60 related cognitive traits. In the first set, 'sensorial synesthesiae,' stimuli to one sense, such as smell, are involuntarily simultaneously perceived by one or more other, additional senses, such as sight and/or hearing. One highly documented case of synesthesia involved Michael Watson (Cytowic, 1993), who synesthetically felt at or within his right hand shapes and textures corresponding to different flavors.

With the second set of synesthesiae, called 'cognitive (category) synesthesiae,' which contains 'ordinal sequence' synesthesiae, certain sets of things that cultures teach us to put together, categorize, and also usually serialize in some specific way – such as letters, numbers, or people's names – get sensory addition, such as a smell, color, or flavor. Common forms of ordinal sequence synesthesiae involve graphemes, numbers, time units, and musical notes. Synesthesiae are usually talked about in terms of the 'inducer,' the sensory stimulus, or cognitive concept which initiates the synesthetic perception, and the 'concurrent,' the synesthetic perception itself. **Figure 1** represents a common set of synesthetically colored graphemes; note that some colors may repeat, that the entire color spectrum may not be represented, that many letters are faint and in shades of gray, and that numbers tend to be brighter primary colors.

The diagnostic criteria for synesthesia are as follows: synesthesia is (1) involuntary and must be elicited; (2) discrete; (3) generic regarding its perceptions; (4) typically unidirectional, but there are rare occurrences of bidirectionality (see, e.g., von Melchner et al., 2000); and (5) noetic (see Cytowic, 1989, 2002; Cytowic and Eagleman, 2009). Synesthesia is known for the persistent invariance of the association between an inducer and a concurrent over time; thus, one of the most common tests toward determining a diagnosis of synesthesia is a 'consistency test' (Baron-Cohen et al., 1987; Rich et al., 2005; Eagleman et al., 2007). Synesthesia is also highly idiosyncratic; the set of correspondences between inducers and concurrents held by one synesthete will have few overlaps with that held by another with the same type. Synesthesia is not a disease, nor, in most cases, a deficit; it is more correctly referred to as a 'trait.'

Figure 1 A typical synesthetically colored set of letter and number graphemes. Copyright by Joy A. Day, 2013.

Regarding visual synesthetic perceptions, about 80–85% of synesthetes who 'see things' do so 'inside the head,' as if the image is projected onto a screen, or just 'in the mind's eye.' The 'screen' is usually located 'on the inside of the forehead' or 'in the eyes,' although, for some, it may be at the top of the head or even in the back, at the base of the skull. For some in this group, there is instead a 'feeling of the color'; for example, the sound of middle C on a piano 'feels' red. These synesthetes have been labeled 'associators.' For those who do see things 'out there,' the images may range from less than a half meter away to fifty meters or more, although most are within the one-half to three-meter range. This latter group of synesthetes is labeled 'projectors' (see Dixon et al., 2004; Rouw and Scholte, 2010). It is possible for a multiple synesthete to be both a projector of one or more types and a nonprojector of other types, or even for a synesthete to be both with regard to one type, varying between projecting and nonprojecting with situations.

Recent studies place the ratio at about 1 in 27 people for finding any type of synesthesia in general across the population (Simner et al., 2006). The percentage of the general human population which has synesthesia varies with the type involved; estimates run from 1 in 250 for basic types of cognitive synesthesia, such as colored graphemes or colored musical pitches, to 1 in 3000 for more common forms of sensorial synesthesia, such as colored musical sounds or colored taste sensations, to 1 in 25 000 or more for people with rare or multiple forms of synesthesia, such as synesthetes who taste the things they touch. Simner et al. (2006) find a ratio of male to female at about 1:1. There are case reports of monozygotic twins, both female (Smilek et al., 2001a) and male (Smilek et al., 2005), in which one had synesthesia while the other did not.

Grapheme to Color

Roughly 1 in every 43 people worldwide has 'grapheme to color' synesthesia (Simner et al., 2006; Day, 2013). A grapheme is a written mark that designates a phoneme, syllable, morpheme, numerical concept, or other concept (e.g., a hand or body movement) via an arbitrary or iconic connection established and maintained by a social group. Phonemes are language-specific categories, each phoneme being a grouping of close, similar sounds that are cognitively generalized to be considered all variants of the same one 'speech sound.' While 'grapheme to visual' synesthesia is commonly referred to as 'colored letters (and numbers),' graphemes also include syllabic symbols, such as in the Japanese katakana system (e.g., 'カ') and ideograms (e.g., Chinese 猫). Likewise, →, ✉, and ☺ are also graphemes, but do not represent phonemic, syllabic, or morphemic elements of any currently written language.

Most research on grapheme-related synesthesia involves phonetic systems such as variants of the Roman or Cyrillic alphabets; yet synesthesia also occurs with systems such as Chinese and Egyptian ideograms, syllabary systems such as Japanese hiragana and Cherokee, and abugidas such as Bengali and Thai. Likewise Braille systems. Thus 'grapheme' transcends the visual to also include (at least) tactile modes. This is said with the awareness that, for many if not most initially sighted people who go blind or learn Braille for other reasons, vision is a major if not primary aspect of reading Braille; and also with the realization that, for those who have never been sighted, 'X to color,' or more broadly 'X to vision' synesthesia will most likely never occur. Nevertheless, for someone congenitally blind, we could encounter, for example, 'grapheme to flavor' synesthesia developing as the person learns a Braille system.

Synesthetes are not uniform in their correspondences between specific inducers and concurrents; for example, not all synesthetes see the letter 'S' as yellow. However, this has led some to the erroneous conclusion that synesthetes are wholly idiosyncratic, and that synesthetes' surrounding cultures and environments will not and cannot play a role in shaping their synesthesiae. Although it is a very rare occurrence, it is possible that the entire set of a synesthetes colored letters may have been shaped by the influence of patterned childhood objects, such as alphabet blocks or colored refrigerator magnets (Witthoft and Winawer, 2006, 2013; Hancock, 2006). However, if such influence does occur, it is more likely to only shape the first four or five items in the series; that is, for example, 'A, B, C, D, E' or '1, 2, 3, 4.'

It is possible for a synesthete to have colors connected to ideographic characters, such as are used in Chinese and Japanese (kanji). In one case study (Day, 2013), a native of Singapore reported on his synesthetic perceptions of 'ma,' which has many different tonal variations, depending upon the language in question (many dialects of Mandarin have at least five tonal forms of 'ma'). The subject provided colors for three of the five basic 'ma' variants: the character for the word 'ma' with a high tone, meaning 'mother,' 媽, is 'strawberry pink'; the character for 'ma' with a fall-rise tone, meaning 'horse,' 馬, is 'chocolate brown'; and for 'ma' with a falling tone, meaning 'to scold,' 罵, is 'charcoal gray.'

For some 'grapheme to X' synesthetes, punctuation and diacritic marks can also adopt synesthetic qualities; an exclamation point (!) might be red, quotation marks (") yellow, and a minus sign (−) in mathematics blue. For most 'grapheme to visual' synesthetes, however, punctuation marks do not take on color, or are all black. Here, we could also consider graphemes such as a 'smiley face' (☺), the dollar symbol ($), or an arrow (→), which may also take on synesthetic colors.

Ramachandran and Hubbard (2003) write, "[t]he font that evokes the most optimally saturated color is usually the simplest – for example, the clean lines of the typeface Helvetica rather than the ornate Gothic. But we have seen rare examples in which an unusual font was more effective at invoking strong color. We suggest that such fonts might serve as ultranormal stimuli that evoke even higher responses from the neurons involved with graphemes […] than more prototypical fonts."

For some 'grapheme → color' synesthetes, uppercase versus lowercase can make a difference; for example, 'B' may be green, but 'b' brown, or 'E' yellow, and 'e' red. It is common for one grapheme to influence the color of an adjacent grapheme; for example, the purple color of '4' could be so impressive and such a favorite that it will change the color of the preceding '2' in the number '24.'

For some synesthetes, not only do graphemes have an associated color, but they might also have a texture, which might only be perceived by a visual aspect (that is, interpreted via shading, color contrasts, and borders), or via synesthetic touch perception. A synesthete, for example, might not only associate the color sky blue with the letter 'E,' but 'E' will also have a 'sandy' texture; the letter 'M' not only magenta, but also a texture of 'wet dew,' or 'like grass with lots of water on it.'

Studies have been done on ambiguous graphemes which can look like either of two letters (see, for example, **Figure 2**), or as either as letters in words or numbers in mathematical figures (such as a line which could be either a '1' (one) or the letter 'I,' or a squared-off angular figure which could be either the letter 'S' or the number '5'). Dixon et al. (2006) found that the synesthetic color of the letter will indeed change for given synesthetes depending upon which grapheme – the letter or the number – the figure is perceived as. This raises the question of whether it is the form or the meaning of the grapheme which elicits synesthetic colors. Dixon et al.'s conclusion was that, for 'projector' synesthetes, it was meaning. However, Ramachandran and Hubbard argue that it is mainly the shape, and not the meaning, which determines the synesthetic response (however, see Ramachandran and Hubbard, 2001a,b). A key element here may be whether the specific test subject observed during a given test was a projector or associator

Figure 2 Ambiguity with the grapheme representing either 'H' or 'A.' Copyright by Joy A. Day, 2013.

synesthete. The question of whether it is meaning or shape which determines the color ties directly to the question of which part of the brain is cross-talking with color-processing areas.

Ordinal Linguistic Personification

Ordinal linguistic personification (OLP) (Simner and Holenstein, 2007) is a form of language-based synesthesia in which graphemes, days, and months are associated with aspects of gender and personalities; for example, the letter 'V' might be perceived to be a confident and indifferent girl, and the number '2' a shy and wimpy boy (see **Figure 3**). Although now seen to be a very common type of language-based synesthesia, we still know very little about OLP. It was first reported in 1893 (see Calkins, 1893; Flournoy, 1893), but was dismissed until recently by most researchers (see Cytowic, 2002; also Day, 2005; Simner and Hubbard, 2006; Amin et al., 2011). It is possible for a synesthete to have numbers which have personalities, but no colors.

Lexeme to Flavor

Another type of synesthesia involves speech sounds or whole words evoking synesthetic flavors (see Ferrari, 1907, 1910; Pierce, 1907; Ward and Simner, 2003; Jones et al., 2011). Here, it is not as the word 'coffee' making you *think* of the flavor of coffee; rather, someone actually tasting the flavor, in his or her mouth, in high detail. But, furthermore, the word 'confess' may likewise have the flavor of coffee, or the word 'microscope' evoke the flavor of carrots. For some of these synesthetes, certain specific speech sounds produce corresponding flavors in the mouth. For example, the hard /g/ sound in the words 'argue' and 'begin' may produce the flavor of yoghurt; the combination of the /s/ and /p/ sounds in the words 'super' or 'peace' may result in tasting tomato soup. This may happen whether the synesthete speaks, hears, reads, or just thinks about the word. The names of food items themselves will tend to taste like the food being named; for example, the word 'sausage' will taste like sausage. Then, certain phonemes of that word will be taken, and those sounds will extend into other words. For example, the 'J' – /d_3/ – sound in 'sausage' also appears in the word 'college,' making it also taste like sausage. 'Phoneme to flavor' and 'lexeme to flavor' synesthetes often also report aspects of texture and temperature as part of their synesthetic experiences; for example, the word 'rake' not only tastes like fried bacon, but is crisp, oily, and rather cold (see Ward et al., 2005). These sensations are felt on the tongue and in the mouth. Unlike with 'grapheme to color' synesthesia, in which, for example, the word 'red' might induce a synesthetic perception of green, a phenomenon known as the 'alien color effect' (see Gray et al., 2006), 'lexeme to flavor'

Figure 3 An alphabet showing an example of ordinal linguistic personification (OLP). Copyright by Joy A. Day, 2013.

synesthesia displays no such effects for the names of foods, such as the word 'bacon' tasting of spinach (Ward et al., 2005).

Ticker Tape

A very rare variant of projected language-based synesthesia is known as 'ticker tape,' in which words, whether spoken, heard, or thought about, are transformed into written text, seen in front of the synesthete. In different case reports, ticker tape synesthesia has appeared as scrolling tape issuing from the mouths of speakers, as cartoon-like balloons, and as subtitles placed slightly above or below the synesthetes line of vision, very similar to subtitled text in movies or on television. Synesthetic ticker tape text is not necessarily always colored.

Other Types of Linguistic Synesthesia

Lexeme to Visual

Lexeme to color synesthesia appears to be significantly rarer than phoneme to color synesthesia. However, case reports do exist, such as that by Weiss et al. (2001), who write about a woman who synesthetically connects colors to the names of only famous people.

Phoneme to Visual

The realm of phoneme or morpheme to visual synesthesia also includes signed symbols in various sign languages. There have been accounts of synesthetes perceiving colors and shapes for signs in American Sign Language, British Sign Language, and Japanese Sign Language (Day, 2013).

Others

Although extremely rare, 'color to grapheme' synesthesia does exist, and can exist without the synesthete having 'grapheme to color.' Other extremely rare types of language-induced synesthesia include 'grapheme to flavor,' 'grapheme to touch,' 'lexeme to odor,' 'lexeme to touch,' and 'phoneme to touch.' Regarding the last, an example given from such a synesthete: "[F]or example, tomato. If it's pronounced 'to-may-to', it's rough like gravel. If it's pronounced like 'to-mah-to', it's softer, like a warm cotton shirt that just came out of the dryer."

For some multiple synesthetes, 'colored grapheme' synesthesia can interact and interfere with other closely related types of synesthesia. Collins mentions her subject *S*, who apparently had colored graphemes, colored phonemes, and perhaps colored names and/or colored geometric shapes. For *S*, with regard to the consonant 'B,' the "[l]ook of *B* is blue (because of liquid roundness of loops making the letter). Sound of *B* is white (due to vowel *e*, which is white). Idea of *B* is blue (is associated with name Betty and a childhood experience)" (Collins, 1929, p. 15).

What Causes Synesthesia?

There are two main overarching theories of synesthesia causation. Both incorporate the idea of there being dedicated areas of the brain which specialize in one or more specific functions. For example, the visual cortex can be further subdivided so as to note those areas that deal specifically with color processing (called the fourth visual areas, or V4 area), or those areas that deal with motion processing (V5).

Many different proposals have been offered toward grapheme to visual synesthesia causation. One theory suggests that cross-activation between grapheme areas and color areas in the fusiform gyrus plays a major role (see, e.g., Ramachandran and Hubbard, 2001a,b; Hubbard et al., 2005). Another theory offers that this form of synesthesia results during processing of graphemic meaning in the anterior fusiform gyrus, when abnormal feedback travels back to posterior inferior temporal regions and the V4 color area (Smilek et al., 2001b). This latter model has been extended by others to consider disinhibited feedback "from a multisensory nexus such as the superior temporal sulcus, posterior parietal lobe, intraparietal cortex or temporo-parietal-occipital junction" (Rouw and Scholte, 2007, p. 792; see also Grossenbacher and Lovelace, 2001; Esterman et al., 2006; Weiss et al., 2005). These two models of grapheme to color synesthesia are not mutually exclusive; both processes could be involved, and could even operate simultaneously, including in a given individual.

It should be pointed out that synesthesia can also result from certain types of brain injury (see, e.g., Jacobs et al., 1981; Vike et al., 1984). This includes cases of synesthesia resulting as part of epileptic seizures (see, e.g., Ulrich, 1903). However, all reported cases of synesthesia induced through injury or degeneration are of the sensorial synesthesia form; there are no such cases resulting in, for example, colored letters, numbers, or days of the week.

Research by Asher et al. (2009) suggests that the following chromosome regions might be involved in specifically 'auditory → visual' synesthesiae: 2q24, 5q33, 6p12, and 12p12. Also, Asher et al. note that the X chromosome apparently is not involved. "The region on chromosome 6 […] has been strongly linked to dyslexia and specifically to difficulties in phonological decoding and orthographic processing, which is of particular interest given the importance of linguistic stimuli in synesthesia. Two genes in this region, KIAA0319 (MIM 609269) and DCDC2 (MIM 605755), have been proposed as candidate genes for dyslexia; both have been shown to play roles in neuronal migration, which has important implications for synesthesia given the evidence for altered neural architecture in the disorder" (Asher et al., 2009, pp. 282–283).

Meanwhile, Brang and Ramachandran (2008) have focused on gene HTR2A, on chromosome 13q. This gene is involved in serotonin reception/inhibition. Brang and Ramachandran are looking specifically at activation of S2a receptors as producing synesthesia, and (hyper)activation of S1 receptors as inhibiting S2a receptors and thus inhibiting synesthesia.

Ramachandran and Hubbard (2001b) have suggested that 'colored number' synesthesia for associator-type could result from abnormal cross-activation between the angular gyrus, which is where concepts of numbers are processed, and the superior temporal gyrus, which processes concepts of color. On the other hand, for projector-type synesthetes, colored numbers might result from hyperconnectivity between the fusiform gyrus, which processes forms, and the V4 areas of the fusiform which processes colors.

There is indication (see Dovern et al., 2012) that those with 'grapheme to color' synesthesia have a higher level of neuronal intranetwork connectivity, and higher rates (about three times that of nonsynesthetes) of both global and specific (medial and lateral visual networks to a right frontoparietal network) intrinsic network connectivity. Diffusion tensor imaging study reveals regionally increased structural connectivity in inferior temporal, parietal, and frontal cortices of grapheme to color synesthetes (Rouw and Scholte, 2007). Research indicates "that in grapheme–color synesthetes, color area V4 showed a significant FC [functional connectivity] with other synesthesia-relevant regions, namely primary and secondary visual areas, auditory cortex bilateral, and right parietal cortex, while in control subjects, V4 was also functionally connected to primary and secondary visual areas but showed no FC with the auditory cortices and the right parietal cortex" (Dovern et al., 2012, p. 7617).

Using diffusion tensor imaging (DTI), Rouw and Scholte (2007) have produced data indicating that hyperconnectivity of white matter structures is involved for at least some grapheme to visual synesthetes. Both 'projector' and 'associator' synesthetes showed greater connectivity in the left superior parietal or frontal cortex than the average for nonsynesthetes. Furthermore, projector synesthetes (but not associators) showed a significantly strong amount of connectivity in the right inferior temporal cortex; thus, projectors could be differentiated from associators based upon the DTI readings. Note that this increase in white matter ties in with theories proposing a genetic predisposition to focused decreased pruning of connections (see, e.g., Maurer, 1997). "Of particular interest is the cluster of greater connectivity found in the inferior temporal cortex near the fusiform gyrus. The fusiform gyrus is involved in the perception and categorization of visual stimuli. Furthermore, an area specialized in the perception of the (form of) graphemes is located adjacent to an area specialized in the perception of colors. This has spurred the idea that grapheme-color synesthesia is caused by cross-connections between adjacently located grapheme and color areas in the fusiform gyrus" (Rouw and Scholte, 2007, p. 795).

Repetitive transcranial magnetic stimulation to the right posterior parietal lobe has been seen to attenuate 'grapheme → color' synesthesia for a short period of time for some (Esterman et al., 2006).

However, brain scan research (see, e.g., Hupé et al., 2011; Hänggi et al., 2011) indicates that the neural bases for grapheme to visual synesthesia are apparently not localized to any specific visual processors, such as the V4 area in the occipital lobe; rather, grapheme to visual is a global neurological process, involving hyperconnectivity and interactions throughout many areas of the brain, some relatively quite distant from each other. Grapheme–color synesthetes might not just have hyperconnectivity between the fusiform gyrus and the intraparietal sulcus but throughout the entire brain, such that synesthesia is only one of many byproducts of these hyperconnections.

Linguistic Turn

Abstract

The 'linguistic turn' is presented in this article from the basis of modern philosophies of language (particularly the contributions of Ludwig Wittgenstein, Martin Heidegger, and Walter Benjamin) and in relation to contemporary adaptations of these philosophical critiques of representation in post-structuralism. The article argues that the linguistic turn occurs when language is taken not as an instrument in social practice but rather as its ground. However, it takes its distance from most 'constructivist' accounts ('social' or 'linguistic') in asserting that such accounts tend to avoid a fundamental engagement with language like the one that characterizes Michel Foucault's study, *The Archaeology of Knowledge*. The argument is made that only a fundamental analysis of this kind can approach the grounds of the social relation.

'The linguistic turn' generally designates in the social sciences a movement away from positivist or historicist accounts of social and historical phenomena toward analyses of the structures of representation that are understood to have helped shape those phenomena. The phrase is frequently (and sometimes loosely) used to characterize contemporary forms of the critique of ideology and the critical 'demystification' or 'demythologization' of historical and socio-political representations that offer themselves as transparent or natural accounts. Since such critical work often proceeds by way of attention to the rhetorical and conceptual articulations of representations that tend to efface their very character as representations, and since it frequently draws from philosophical and even literary theories of language and representation, it is understood to participate in a turn from socio-historical 'realities' to their linguistic presentation.

The phrase is used so broadly, however, that its strong meaning for theoretical methodology is frequently lost. Frequently, the critique of representational structures proceeds without a consequent attention to the question of language, and even some of the strongest versions of 'linguistic constructivism' fail to interrogate their own presuppositions. Thus, the linguistic turn will be defined here fairly strictly from the basis of its foundations in order to recover its meaning and implications for the social sciences. It will be defined as beginning when language is no longer understood as an instrument in social practice, but rather as the site or 'ground' for such practice. It will be understood to have been fully undertaken when such a fundamental understanding of language shapes the procedures of the sciences themselves.

The beginnings of the linguistic turn may easily be traced to the eighteenth century and seen to be lurking in the very rich debate concerning the origins of language. It is clearly occurring in the research of Wilhelm von Humboldt and in the writings of the German Romantics, and then actively recognized – some would say, practiced – in the later works of Friedrich Nietzsche. Thus, when the official occurrence of a linguistic turn is registered in Vienna for philosophy of language, a more 'fundamental' turning is already long underway in the tradition of German philosophy that Walter Benjamin and Martin Heidegger brought to the fore in their remarkably convergent speculative writings on language. Indeed, if Ludwig Wittgenstein himself was ready to grasp in 1929 the import of Heidegger's still largely latent meditation on language and the significance of Heidegger's own linguistic practice, it is because the philosophical ground was well prepared for Heidegger's subsequent turn (his famous *Kehre)* from an existential philosophy still marked by the metaphysics of the human subject to a thought of what is given of Being in and by language.

Historians of the social sciences will provide ample testimony of methodological tremors linked to the developments noted here in philosophy of language – in short, a displacement of the human subject or human consciousness as the grounding source of meaning in signifying practice, and the requirement of rethinking the subject/object relation and relation itself. However, it may well be argued that the strong turn realized by authors such as Benjamin and Heidegger is not assumed in the social sciences in Europe until the period of the structuralist movement (a movement that explicitly unseated human consciousness from its founding role in favor of broader structures of determination: kinship systems, linguistic structures, and the laws of sexuality or desire). Even here, however, the turn to language remained frequently at no more than the level of analogy, and systems of myth or kinship were shown to be formalized equally effectively with recourse to mathematical logic (another form of appeal to a *logos*, some would argue). Thus, while structural linguistics functioned as a kind of 'point science' for the initiatives throughout the human sciences in Europe for over a decade, only the endeavors of 'post-structuralist' authors such as Michel Foucault, Jacques Lacan, Jacques Derrida, or Gilles Deleuze actually carried the notion of the linguistic constitution of being to its full import for the social sciences. Only from the time of post-structuralism did it become possible to entertain thinking the social relation from language.

The linguistic turn has thus occurred, for example, when Michel Foucault, in his methodological treatise *The Archaeology of Knowledge* (1969), announces that the fundamental element for his study of discursive formations will be the *énoncé,* the statement. In an effort to displace the governing categories of the history of thought (totalizing categories that establish continuity and that all lead back, in Foucault's view, to the sovereignty of the human consciousness), Foucault attempts a theoretical elaboration of a discursive 'object' that is always relational and always to be thought from its material

emergence. 'Object' must be left here in quotation marks because the statement, as Foucault understands it, is the 'modality' or 'function' of existence of discursive facts, what 'gives' them or enables them to occur as language and thus as (1) a relation to a domain of objects; (2) a set of possible positions for an enunciative subject; (3) an element in a coexisting discursive field; and (4) a repeatable materiality. A statement, in Foucault's definition, cannot be understood as a sentence that lends itself to hermeneutic investigation or logical analysis, but must rather be seen as the material, always relational, condition for something like a sentence or a proposition. Historical analyses that seek the 'signified' of any group of signs (reading any document for the meaning it bears, any text for its 'allegorical' sense), like linguistic studies that seek rules of formation, invariably efface the irruptive, eventful character of the fact of language, returning all linguistic events to their organizing conditions. Thus they participate in what Foucault calls, in his famous *Discourse on Language*, the 'ancient elision of the reality of discourse'. Foucault's effort in thinking the *énoncé* as the material function of existence of any discursive act or organization is directed at honoring the 'anarchic' character of language – a potential for disruption which 'disciplinary' and institutional formations seek to channel and control. At the heart of his project is an assumption that the orders of knowledge and the social institutions in which they are embedded are organized by a fear of the undermining, or even violent dimensions of discourse for the orders in which it emerges (undermining for the mere fact that it can reveal the inherent lack of foundations for the social order, violent for the fact that it can carry the irruption of desire):

> There is undoubtedly in our society, and I would not be surprised to see it in others, though taking different forms and modes, a profound logophobia, a sort of dumb fear of these events, of this mass of spoken things, of everything that could possibly be violent, discontinuous, querulous, disordered even and perilous in it, of the incessant, disorderly buzzing of discourse.

Of course, Foucault's own study, fiercely abstract in its unfolding design, is not without its own violence. Indeed, his *Archaeology* sometimes reads as a veritable storm of theoretical elaboration; its winds tear unrelentingly at the foundations of the history of thought. But a glimpse at the virulence of reaction on the part of proponents of rational norms of 'communicative transparency' and/or pragmatic 'consensus' provide a clue to the explosive potential of Foucault's effort to honor the disruptive dimensions of language.

Numerous authors have pursued Foucault's 'archeo-logical' analyses of discursive formations; in fact, significant currents in the growing field of cultural and 'post-colonial' studies principally draw upon Foucault for their understanding of the discursive constitution of social reality. Theories of social construction are deeply indebted to his analyses of 'disciplinary' knowledge and mechanisms of control. Far fewer authors have carried forward his understanding of the subversive dimensions of the enunciative act, though one sees its impact in the fields of gender studies and sexuality or in a topic such as the study of 'the practices of the everyday' by Michel de Certeau. It is for this reason that one might regard the 'linguistic turn' – which many would undoubtedly anchor in the widespread acceptance of the theory of linguistic or social 'constructionism' – as incomplete and even faltering. Theories of social construction, and even theories that stress the necessary 'performative iteration' of social norms, almost inevitably turn short of the engagement with language that marks Foucault's work (or that of the other 'post-structuralist' authors to which I referred). They fail, in particular, to attend to the materiality of discursive usage in that dimension that involves what I might term an enunciative experience with language. This avoidance is easily attributable to Foucault's own wariness regarding the 'ontologizing' and 'transcendentalizing' sources upon which he silently draws (principally Heidegger), not to speak of his strictures against anthropomorphism and humanism. But Foucault's own turn to ethical questions in his late work point firmly to the necessity of an exploration of the subject's engagement with the fact of language at the fundamental level evoked in the *Archaeology* – with the fact and manner of the way the *énoncé* is given in its material singularity. What dimension of experience is engaged with this 'gift,' and what engagements (to evoke a motif pursued throughout Jacques Derrida's late work) does it presuppose if the relations offered by the *énoncé* must be thought from the way they are brought into existence in singular instances of usage?

Heidegger had attempted in his later meditations on language to name with precisely the term 'usage' the human relation to the fact of language. To avoid turning language into a kind of transcendental horizon (a trap into which many 'linguistic constructionists' inevitably fall), and to hold to a thought of its finitude, Heidegger attempted to think through the necessity of a human 'accession' to language – i.e., the conditions for any 'interpellation' of the human subject by language, and any human response. He did not avoid a certain anthropocentrism in this undertaking, but he also pointed beyond the purview of the metaphysics of the human subject. Unfortunately, few authors have followed through Heidegger's thinking on this crucial point, though among them we may count the French psychoanalyst Jacques Lacan (whose thought of the category of the 'real' presupposes this understanding of the 'human relation to the signifier') and the French writer Maurice Blanchot, whose enormous influence on 'post-structuralist' thought still remains to be measured. But their work, taken together with that of the distinguished Jewish philosopher Emmanuel Levinas and the more recent work of authors such as Jean-Francois Lyotard and Jean-Luc Nancy, make it possible to pursue a thought of the manner in which the social relation opens in and with language. From a notion of the human engagement with language, they elaborate an understanding of the event by which human speech communicates a form of 'finite transcendence': a transcendence of determined orders of meaning that is first of all an exposure to the other human being. They thus make it possible, in effect, to return to a thought of the social relation like that approached by Hannah Arendt in *The Human Condition* (1998) in her effort to rethink the notion of public space and the political act itself.

This latter thought of 'communication' (not a transparent communication of signified meaning, but rather, as Walter Benjamin argued so powerfully, a communication of the very possibility of relation) clearly carries with it the obligation of

defining the conditions for its engagement in critical or theoretical practice. For it is clear that the pertinence of a traditionally 'theoretical' mode of inquiry must come into question once language is engaged at levels that exceed that of its representational or instrumental function. Once a 'saying' that bespeaks the irreducible presence of an enunciating subject becomes the object of a meditation on the grounds and possibility of community (but this can be no 'object' for description), theory can no longer claim an exclusive purchase on the question of the social relation. Or it must rethink its own discursive modality and its relation to others (to the language of literature, for example). The challenge of the linguistic turn for the social sciences thus bears upon the discursive practices of the sciences themselves. It is not a challenge that requires the social sciences to abjure their commitment to clarity and rigor in analysis, but it does require them to entertain the question of their own discursive usage and the possibility of translation between discursive modes or between their own usage and that of a singular event of language. Here, it becomes clear that a fundamental reflection on linguistic usage is the very condition for a consequent engagement of the social relation – a relation that is not reducible to its linguistic determinations, but also not thinkable apart from the site of its emergence and articulation. The 'linguistic turn' is not a methodological 'given,' a path already secured; it is a required turn to the grounds of meaning that must be repeatedly undertaken if social analysis is to achieve concreteness in its effort to regain the social itself.

Abstract

Discourse analysis is the preferred method of historians who have taken the turn toward a view of language as the dense and autonomous site in which the objective reality of the past and the subjective identity of the historian is constructed. 'Discourse' refers to the framing assumptions of thought, speech, and action in particular epochs and cultures and/or to the communicative processes that characterize both development within and interaction among semiotic or cultural systems. Historians affirm the plurality and heterogeneity of discourses as a condition of historical change. They are divided about the relation between discourse and its 'others,' particularly the 'other' of material practices, and about the ways in which the production of individual and collective identities within discourse affects the status of historical agency.

The Linguistic Turn and the Post-Modern Epistemological Crisis

The term 'linguistic turn' emerged as common currency in discussions among historians during the 1980s and 1990s to designate a sweeping, but vehemently contested, shift in the framework within which both the object or content of historical investigation (the 'past') and the methods of achieving historical knowledge of this content were defined. In its weaker, least contentious, form the linguistic turn referred to a more intense and focused attentiveness to the opacity and complexity of the linguistic forms through which all evidence of the past was mediated, and the 'truth' of the past represented, reconstructed, and communicated. The term itself was appropriated from discussions among philosophers, where it had been used as a general description of the turn in twentieth-century philosophy toward reformulating the epistemological problem of the relationship between thought and reality in terms of a relationship between language and reality. In the stronger and more contentious form that surfaced in debates among historians, however, the linguistic turn came to designate a shift away from the conventional view that language was a passive, potentially transparent instrument for transmitting content, for organizing, representing or expressing the truth of a reality outside of itself, and toward a view of language as the dense, fertile and autonomous site in and through which the objective reality of the world as well as the subjective reality of language users was actively produced or constructed. From this latter perspective, the act of taking the linguistic turn was synonymous with the claim that the production and communication of historical knowledge was inextricably entangled in the epistemological crisis associated with the transition from a modern to a 'postmodern' cultural condition.

As a particular disciplinary expression of this epochal transition to postmodernism the linguistic turn in history was grounded on three major premises. First, it accepted the ultimate futility of the historical quest to reconstruct a single, coherent narrative of human history whose pattern or structure could somehow be grasped and mapped in its totality from a transcendent position outside of the particular, contingent meanings that human beings in specific times and places had imposed on the material traces of the past, a quest most recently articulated in the national liberation narratives, global modernization theories, and Marxian historical dialectics of the Cold War decades. Second, the linguistic turn appropriated from poststructuralist theory the sweeping critique of residual beliefs in the existence of noncontingent stable identities (whether natural kinds or metaphysical essences) whose fates might be traced historically through paths of accident, evolution, repression, resistance, and liberation. National, ethnic, racial, sexual, gender, and class identities were not treated as material or metaphysical realities expressed in language and culture, but contingent, constantly changing, constructions produced in language and culture. Third, this dissolution of essential identities implied a transformation in the methods of historical representation. Access to a reality not already shaped and constructed by the linguistic medium in which it was always presented to the knower, either as subjectively lived experience or objectively perceived external object or event, was considered impossible. The historian could only interpret interpretations, could only redescribe and thus reconstruct in his or her own language the linguistic constructions of others.

Various elements of the epistemological crisis associated with the linguistic turn had been present in muted and sometimes more extreme forms within the Western historical tradition since the beginnings of the modern professionalization of history in the early nineteenth century. During the post-World War II era the disconcerting relativist implications of self-consciousness about the density and relative autonomy of the linguistic medium that mediated reality as meaningful was reined in by a broadly shared disciplinary consensus concerning the reality of the past and the methods that provided access to its truth. The more radical linguistic turn of the 1980s, with its implications that the historian's past was a construction grounded on ethical and political choices, rather than on epistemological criteria, was associated with the breakdown of this consensus, as the increasingly effective voices of previously excluded perspectives, particularly those of women, ethnic minorities, and former colonial subjects, mounted a powerful critique of established professional conventions. The linguistic turn was embedded deeply in the feminist, multiculturalist, and postcolonial 'turns' among dissident members of the disciplinary community, and connected to a new series of

interdisciplinary liaisons with literary theory, cultural anthropology, and philosophy.

A major difficulty standing in the way of providing a concise description of the linguistic turn in history stems from the diverse meanings assigned to the term 'language.' The everyday conventional meaning of language as a native or vernacular language is rarely what contemporary historians have in mind. In fact, the use of the term has been extended broadly beyond the rules and practices of verbal communication in speech and writing to include nonlinguistic structures of exchange and all signifying practices through which meaning is produced, transmitted, and communicated. As the totality of meaningful action or signifying practices, 'language' becomes virtually indistinguishable from 'culture.' The favored model for organizing discussions of language by proponents of the linguistic turn during the 1980s and 1990s was the semiotic model derived from the linguistic theories of Ferdinand de Saussure and Charles Sanders Pierce, in which language is conceived as a structured system of 'signs' whose meanings are determined by their relations to each other rather than their relation to a 'transcendental' object or subject. Most influential for historians has been the development of this semiotic model in cultural anthropology and especially the French structuralist and poststructuralist theory of Louis Althusser, Roland Barthes, Jacques Derrida, Jacques Lacan, and Michel Foucault. Although 'language' and 'discourse' are still often used interchangeably in debates concerning the linguistic turn, the attempt to provide some kind of theoretical focus on the analysis of language in history has increasingly been organized around the term 'discourse.' Historians who have taken the linguistic turn tend to define the distinctiveness of their own signifying practice as 'discourse analysis.'

Discourse Analysis: Enabling Structures and Communicative Practices

Despite the widespread use of 'discourse' as an organizing concept within a variety of the humanistic and social scientific disciplines, its meanings have remained fluid, flexible, and often indefinite. However, the two general meanings of the term in common usage – (1) a formal speech or treatise that presents a theme or object in a systematic and authoritative manner, and (2) a conversation or discussion involving a communicative exchange among a number of speakers – provide a framework for the more technical, disciplinary uses within current historical work.

Discourse as the Historical a priori of Thought, Speech, and Action

The more formal, systematic, and authoritative dimension of discourse is articulated in historical studies in the attempt to outline the formal structures of rules, codes, categories, and procedures (the relatively stable aggregate of conventions, usages, idioms, tropes, vocabularies) that define a particular communicative space, delimiting the field of possible statements and actions, enabling what can be meaningfully and effectively articulated. Historical discourses in this sense are impersonal formal structures operating anonymously behind the backs of speakers and actors, constituting the world of objective reality and subjective agency by making certain types of speech or behavior possible and other types impossible, by recognizing certain speakers and actors as legitimate or effective, and excluding others as illegitimate or ineffective, by defining certain objects and events as real or objective, and others as fictional and subjective. Different discourses constitute the world of experience in different ways, and are thus incommensurable with each other. They produce homogeneity (within their field of power) and heterogeneity in relation to other discursive fields. Specific statements or actions are only meaningful as instances of the rules and regularities governing the discourse in which they occur. Discourses become markers of the stable, synchronic, self-contained, incommensurable, discontinuous dimension in historical systems of meaning or cultural formations. For the historian, mapping the structures or codes of particular discourses defines historical action and historical actors as determined by those structures, as events and agents in a foreign world that has its own criteria for determining what is true or real, who is an effective agent, whose speech is meaningful. Discourses may thus, in Foucault's terms, create specific historical 'regimes' of truth and systems of power.

Discourse analysis can be a way for the historian to establish the otherness of the past, as it has been by practitioners of the new cultural history who imagine the past as a 'foreign country.' Textual traces from the past can be provided with their own reality, differentiated from the realities of other times and places, by inserting them into the discourses that originally defined their significance. By recognizing the strangeness, the alien character of the 'voices' or 'traces' from the past deposited in the archival record, the present also comes into focus as a particular historical moment with its own sets of systematic enabling and limiting conditions. In this sense the deployment of an ahistorical, formal conception of discourse can produce a very concrete historical consciousness, an awareness of the contingent historicity of present existence. It provides few guidelines for reconstructing the developmental processes that lead from the past to the present.

Discourse as Communicative Process

As a constitutive system of categories and codes that differentiates historical worlds or cultures from each other, discourse becomes a tool for the reconstruction of past as different, for marking historical distance and avoiding anachronism. But it also freezes systems of meaning into static cross-sectional snapshots that allow analysis of the self-relating structures of individual systems, but do not illuminate the interaction among systems or the processes of transformation from one system to another. Moreover, the employment of the structural definition of discourse as a closed semiotic system seems to dissolve historical agency. The identity of agents is called forth or constituted by the discourse itself and their statements and actions remain mere instances of the discursive rules that produce the reality in which they operate. A second dimension of discourse analysis, however, breaks apart the apparent stasis and structural determinism of this stance. Conceived on a conversational or dialogical model in which signifying practices operate in continuous processes of confrontation, exchange, and transformation, discourse becomes a term for

conceptualizing historical change, communicative interaction, and the dynamics of historical agency. From this point of view, linguistic or signifying actions are not authorless events in language but actions on language by individual and collective agents who appropriate inherited possibilities contained in existing discursive structures in order to both modify those structures and to transform themselves as agents. But how could the agents, the individual, and collective identities contingently and historically constructed within the structures of discourse, become themselves the creative transformers of discourse? One possible answer to this question could be constructed from within discourse theory itself, but ultimately it does raise the issue: what is the 'other' of discourse? and how is discourse changed and transformed in its relationship to its other?

Discourse and Discourses: Pluralism and Heterogeneity

In an early manifesto of discourse analysis, Foucault (1972) distinguished between a general domain that included all meaningful or signifying actions and their formal or structural conditions, and more individualized, singular groups of signifying practices organized in a focused disciplinary fashion around the construction of a coherent regime of truth. Historians have not been completely disinterested in the more sweeping, universalizing or totalizing notions of discourse that define the historical a priori of whole epochs or cultures, like the discourse of 'man' or secular historical humanism that rules over the 'modern' epoch, but they have tended to gravitate toward a practice of discourse analysis that emphasizes both the plurality of discourses and the conflict among discourses within a general discursive domain. Three forms of such heterogeneity in discourse analysis are particularly obvious. First, discourses can be differentiated in terms of the social and cultural dimensions or spheres in which they operate or are effective. Thus, one might differentiate among public, official, popular, literary, elite, urban, or religious variants of discourses of class or madness or justice or gender at any particular time or in any particular geographic area. Second, discourses obviously are differentiated in terms of the specific domains of meaning and action – the objects, subjects, and rules of relationship – which they construct. Thus, orientalist discourse constructs 'the east' as well as the 'orientalist'; psychiatric discourse constructs the psyche and the psychiatrist. Differentiations of this type are often imagined as analogous to academic disciplines that produced their putative objects of analysis in the way that the discipline of history constructs 'the past,' or sociology constructs 'society' or 'the social.' Third, historians tend to differentiate competing or alternative discourses that operate within these various dimensions and domains. Within the dimension of public discourse, for example, there may not only exist separate discourses pertaining to the spheres of political authority, citizenship, social hierarchy, or legal structures, but also dominant and oppositional, liberal and conservative, patriarchal and feminist, bourgeois and working class discourses that delineate the boundaries of this sphere and organize and define its contents and relations in competing and conflicting ways.

This proliferation of difference in the discursive realm is one of the major conditions of creativity and historical change. At any particular moment in time an historical actor will inhabit a heterogeneous compound of discourses, dissolving the apparent formal disassociation of discourses from each other, allowing for creative performances in which the inner logics of different discourses are brought in contact with each other in transformative ways. Just as a scholar can inhabit an interdisciplinary space in which various disciplinary discourses can be brought into interaction in order to transform conventional, dominant discourses about a particular issue or problem, an actor in the public sphere might exploit the plurality of existing constructions of citizenship in various inherited discourses to imagine and act out innovative forms of membership and responsibility in a political community. The first task for the historian engaged in discourse analysis is to identify a discourse within a given body of evidence, to map out its boundaries, and reconstruct its inner logic or structure. A discourse is not simply a synoptic summary of the aggregate of statements that refer to some specific theme, like references to the work of women in France between 1815 and 1848. To identify the discourse in such thematically associated material would be to reconstruct the formal dimensions within the signifying practices informing the evidence. Discourse would be the organizing power that constructs the 'world' the evidence assumes and provides effective power to certain statements. Once such a discourse has been mapped or reconstructed, the map can be used, like an 'ideal type' or 'paradigm' to identify or discover its presence in other texts or bodies of evidence. Such reconstructive mapping of historical a prioris establishes historical difference, marks off the conditions of possible action and expression in different worlds. The second task of the historian of discourse, however, would be to cut through or modify the radical difference produced in the first operation – to describe the ways in which the specific actions – linguistic and nonlinguistic performances with communicative intent – within the formal conditions of a discourse create changes in that discourse and reveal the porous, contingent nature of discursive boundaries. This model of discourse analysis as a constant oscillation between the reconstructions of formal contexts and concrete, innovative performances in a dialogical, communicative context has been highly developed within specific realms of intellectual history – like the history of political theory, public opinion, and ideology, but its expansion into a broader analysis of the whole range of historical practices has highlighted a number of problems, problems that have become the center of the controversies dividing historians about the validity of discourse analysis per se.

Discourse and its 'Others'

Discourse and discourse analysis only attain distinctive, specifiable definition if they are placed in relation to something which they are not. What are the 'others' of discourse? This question is directly relevant to two questions that are of particular interest to historians: How can one explain the stability and/or hegemony of certain discursive formations among specific populations over extended periods of time, and how can one explain changes within specific discourses, the shifting relationships among discourses, and the emergence of new discourses in time?

Discourse and the Material World

The polemical thrust of discourse analysis when it emerged as an articulated position in debates among historians during the 1980s was directed primarily against dominant conventions of historical analysis which portrayed the realm of the production, reproduction and transmission of meaning in linguistic and other signifying actions as a product, effect or expression of the structures and transformations of material practices. Despite the complexities within and obvious differences among class oriented British cultural Marxism, the sociologically grounded modernization narratives prevalent in the US and Germany, or the structuralist 'total histories' of the French Annales school, all were viewed as ultimately reducing the production and transformation of meaning to an effect, however indirect, of changes occurring outside of the linguistic and more broadly cultural sphere. Concepts like 'ideology' or 'collective mentality' were criticized and often rejected outright because of their implication that the production of meaning in language could only be grasped with reference to a reality or truth that was situated in material social practices outside of language. In its initial stages the linguistic turn often appeared as an attempt to resist the absorption of the cultural into the social, to insist on the autonomy of processes of meaning production, to assert the autonomy (no longer 'relative') of intellectual and cultural history. More serious tensions among historians developed, however, when the realm of discourse was conceived as creating the categories and identities through which people lived their social being and defined their social interests. Class identities were not defined as public expressions of the ways in which groups articulated social interests grounded in the way they lived their relation to nature in systems of production, but identities produced in discourse that determined how interests were defined and the ways in which economic and social relations were experienced. Gender differentiation in public discourse, or medical discourse, or class discourse was not conceived as representing the contrasting realities of social experience of physically differentiated bodies but as constructed forms in which bodies were experienced as sexually different. Histories of the experiences of classes, of the sexes, of races, ethnic groups, nationalities, colonial subjects, etc., were transformed into historical reconstructions of the discursive processes through which class, sexual, racial, ethnic, national, and colonial identities were constructed.

It would be misleading however, to treat this new cultural history, grounded in discourse analysis, as some historians have tried to do, as a new form of idealism based on a belief that language makes the material world, that thought creates existence. First, in discourse analysis, discourse itself is conceived as a dense network of signifying practices, a material activity embedded in the communicative interactive relations between producers and consumers of meaning and articulated in institutional structures. The linguistic turn did not simply exalt the status of language but changed the conception of what language is and how it works in history. Second, the 'other' of discourse analysis is not the empirical analysis of concrete evidence: discourse analysts certainly are as attentive to archival evidence as any social historian. The other of discourse analysis is a belief in the ultimate accessibility of an 'unmediated' meaningful reality on the other side of discourse which determines the truth of the meanings produced within discourse. Discourse analysts restrict the historical task to reconstructing the conflicted process of the cultural mediation of meaningless 'reality,' the practical human activity of meaning construction, transmission, and transformation. Yet the actual practice of discourse analysis may raise doubts about historians' ability to finally extirpate the metaphysical impulse to represent a truth beyond the represented 'truths' of human cultural practices. In the work of Michel Foucault and many of the historians who follow his lead, for example, one finds an assumption that the actual workings of discourse are determined by a prior will-to-power, by a universal drive to impose meaningful order on meaningless 'reality,' to narrativize the disassociated fragments of experience, to stabilize the endless proliferation of contingent identities. Discourse analysis, thus, not only marks a turn from the social to the cultural, but also a turn toward the political in the ubiquitous sense that all practices in the world have a political intent, that the legitimation, expansion, and consolidation of power is not a particular sphere of historical action, but the form of all historical practice. Discourse analysis has also been characterized by a renewed and transformed interest in the history of the body and of nature. Both the human body and the world of external nature are constituted within discourse, but at the same time are primary sites of resistance to any particular discursive construction. Within the framework of discourse analysis human and nonhuman physicality cannot have a positive unmediated reality of their own, a reality capable of self-representation within its own nondiscursive, transcendental 'language.' Bodies may be constantly inscribed and re-inscribed as meaningful in various discursive networks, as laboring organisms, as reproductive mechanisms, as emblems of spiritual content, but their sheer intractable existence also marks the limits of discursive constitution and thus fuels an infinite process of re-inscription and re-constitution.

Discourse Analysis and the Problem of Historical Agency

Discourse analysis is premised on the claim that effective historical agency, and thus the existence of individual and collective subjects who are capable of productive, creative, transformative action in the world, is produced in history rather than expressed in history. It is not subjects who produce meaning, but the networks of meaning that create subjects. In some earlier forms of discourse analysis, which was heavily tilted toward an analysis of the homogenizing, totalizing regularities in discursive structures, subjects, or authors often appeared as nothing more than anonymous, replaceable bearers (*Träger*) of the structures that defined them. In many ways this conception of discourse as a systematic process of meaning production mirrored the position of social historians who defined individual and collective agents in history as the inhabitants of social functions, or as bearers of the process of material production. Historians who took the linguistic turn in the 1980s and 1990s, however, were concerned with revealing the historical contingency of determining structures, with deconstructing systems of meaning production that allowed

certain identities – of class, race, gender, ethnicity, and so on – to be experienced as natural realities or metaphysical essences. Attentiveness to the conflic tual, dialogical, communicative dimensions of discourses in which historical identities were constantly constructed, modified, dissolved, and transformed did assume the effective agency of historical subjects (both individual and collective) who were able not only to negotiate among conflicting, multivocal, sometimes contradictory discourses, but also to redefine themselves as subjective agents.

Discursive agency, however, was decentered and contingent, the agency of constantly shifting 'identities' that were the creations of discursive practices themselves. Historical subjects were 'subjected' to the logics of the various discursive networks that they inhabited. But within the limitations defined by historical situation and status they made choices that might ultimately change that situation and status, and thus also their own identities. The question of agency in discourse analysis was not so much whether or not agency was possible within its terms, but what kind of agency was imaginable. Within the complex heterogeneous compounds of any cultural or discursive formation, a particular individual might simultaneously inhabit a whole series of dispersed, fragmented subject positions. Within each of them – as parent, worker, consumer, or as sexual, racial, or national subject – the individual could act, either individually or by identifying himself with other individuals similarly positioned in various discourses, to shift the hierarchical relations among identities, and to change the identities themselves. In discourse analysis, human agency, the identity and effectiveness of the individual and collective subject, was construed as an always coming-to-be in worldly particularly, as historical through and through.

This historicization of agency was at the same time a politicization of agency. The effective construction of specific collective identities, like nation, class, or race was described as a conflictual political process in which certain subject positions were excluded or privileged, became dominant or were repressed, attained stability through forceful imposition on others, or were negotiated in a more consensual fashion. The historicization and de-centering of human agency in the many historical works devoted to the cultural or discursive constructions of class, gender, national, or racial identities written during the late 1980s and through the 1990s did not fully expunge questions concerning the extralinguistic, culturally 'transcendent' grounding or foundation of human agency among historians. The writings of intellectual mentors of the linguistic turn, like Foucault, Walter Benjamin, or Jacques Lacan (and, in the1990s, Slavoj Zizek), were replete with references to the problematic nature not only of the physicality of the body but of the transcendent autonomy of some form of un mediated subjectivity – that which sought or was given shape and identity in the various 'subject positions' constituted in discourse – which appeared to be a necessary condition for the historical differentiation and transformation of subject identities. Historians might modestly decline professional competency in addressing such questions. But that which was outside discourse analysis inevitably shaped what occurred inside discourse analysis. The metaphysical limits of discourse analysis suggested that discourse analysis was itself a historical, that is, contingent and particular identity, a 'subject position' for historians of a particular place and time.

Discourse Analysis and the Discourse of Historians

The linguistic turn in history began with, and has continued to be characterized by, an intensive self-reflexive focus. With the publication of *Metahistory*, White (1973) introduced many historians to discourse analysis as an analysis of the discourse of historians. The primary object of concern was not so much the reconstruction of the way past identities were produced in language, as the construction of the individual and collective identities of historians through their discourses about the past. Stories historians told about the past were unveiled as stories in which they fashioned themselves, and possibly their readers, in the present. In the discourse on historical theory and historiography instigated by White's work, historians' texts are analyzed as linguistic artifacts akin to the rhetorical and fictional texts of literature, in which the structures of the linguistic form determine the 'objectivity' of the content. The discourse of objective realistic representation that had conventionally legitimated entry into the disciplinary community devoted to knowledge of the past was displayed as a mystifying, self-deceiving attempt to portray the subjective (that is, based on ethical and political considerations) construction of its object as a true representation of its object. The goal of such analysis was self-recognition and emancipation.

Once the burdens of determination by the putative objective reality of the past were recognized as self-imposed limitations, historians were free to imagine and construct alternative pasts in terms of their ethical and political commitments in the present and their visions of alternative futures. Moreover, as soon as the texts inherited from the past were grasped as historically contingent discursive constructions of meaningful identity in time, the inhabitants of the present could recognize themselves in them, not just constitute themselves through them. History could become a discovery of the 'reality' of the human past which was in itself a constantly reformulated attempt to represent reality as meaningful.

Two major questions continue to fuel the debate instigated by the analysis of the historical discipline as a discursive community. The first concerns the politics of this disciplinary community. How should the boundaries of legitimate historical discourse be determined in relation to other disciplinary discourses, or what are the limits of interdisciplinary crossing if history is to maintain a distinctive identity? Within the terms of discourse analysis this question must be decided through the communicative practices of historians rather than through an appeal to the object of analysis. The question then becomes one of defining the discursive process in which historical reality and truth are represented. Who is recognized as a 'subject' with rights to participate fully in the discourse, and how are the negotiations within this discourse to be regulated? The problem of reconstituting a common past becomes a political issue of extending membership and of democratizing power within the profession. Solidarity and objectivity are inextricably bound up with each other. One of the reasons that the linguistic turn and discourse analysis have become such

contentious issues among historians is that they pertain directly to the identity of history and the identity of historians.

The second issue raised by the reflexive moment in historical discourse analysis relates to the more general issue that troubles the whole debate surrounding the linguistic turn. What are the ethical (and political) implications of construing the past as a construction of discourse? Is the creation of an inclusive, democratically negotiated consensus about the nature of the past adequate to the goal of recreating the reality of the object of historical investigation and defining the criteria of historical knowledge? As the ongoing debates about historicizing the Holocaust have suggested, discourse about the truth of the past must involve the dead as well as the living. To converse with the dead entails a recognition not only of their physical existence, their extradiscursive 'reality' as bodies that transcend all the meanings inscribed on them, but also their status as actual or potential subjects of a discourse of their own that must be taken into account in any discourse we might construct about them. It would seem that an adequate conception of historical discourse would need to include some recognition that historians' discursive production of the past can be interrupted by the voices of the dead, and that a part of the ethical obligation of the historian is to listen to those voices.

Linguistic Typology

Abstract

Modern linguistic typology is a method in language universals research. Implicational statements in the form of 'if X, then Y' are drawn based on cross-linguistic distributional patterns of existing and nonexisting types. These statements constitute language universals delimiting the range of possible human languages; for example, a language with X property but without Y property is excluded from the possibility. A functional, as opposed to a structuralist, typological approach allows comparison of languages in term of functional equivalence/disparity rather than in terms of categorial and structural properties, which differ from one language to another.

Linguistic typology evolved from a nineteenth-century attempt to classify the languages of the world and to ascertain possible variation among them. While the current practice in typology essentially retains these goals, modern typology differs from classical typology in its scope and methodology. Instead of typological characterization of an entire language, specific phenomena or individual constructions are studied. Constraints on possible variation are stated in terms of implicational universals derived from the distributional patterns of existing and nonexisting types. Typology is nowadays considered as a particular method of linguistic investigation. In contrast to other formal approaches to grammar, such as Chomskyan generative grammar, the typological method is functionally oriented in that what is sought is the typology of the relations between function and form and in that it seeks external explanation for the observed patterns. A careful study of different types of language suggests that languages may differ more radically in the organization of grammar than believed in the latter half of the twentieth century. It is likely that cross-linguistic similarity is more profitably sought in the functional equivalence and similarity than in the ways languages define and organize grammatical elements (see Section Typological Differences in Clausal Organization below).

The term typology in linguistics, as in other fields, is generally understood to mean the classification of languages in terms of structural types. However, from the very beginning in the history of typological investigation, classification itself has never been the ultimate goal. For the grammarians of the early nineteenth century, exhaustive classification of the world's languages was a way to answer the question of what is possible variation in human language. For modern linguists, typological classification is part of a method for discovering the constraints governing possible human languages or possible grammatical constructions.

Typological classification is frequently contrasted with the genetic classification of languages and is often characterized as a historic in its orientation. This was also not the case in the beginning of the typological studies in the early nineteenth century, when genetic and comparative approaches were not clearly distinguished from the typological one. Indeed, it was in the context of developing a program of comparative historical research in his 1808 book, *Über die Sprache und Weisheit der Indier* (On the Language and Wisdom of the Indians), that Friedrich Schlegel (1772–1829) developed a typological framework most famous in the history of typology. It was mainly due to the structuralist context, in which modern typology arose, that it countenanced a synchronic outlook. In contemporary typological scenes, dynamicization of typology, as propounded most forcibly by Greenberg (1969, 1995), is fast obliterating the view that typology is a purely synchronic discipline.

Classical Typology

In the abovementioned book, Friedrich Schlegel proposed what is believed to be the first typological framework, according to which the languages of the world are classified into two types – flexional (or inflectional) type and affixing (or agglutinative) type. Though later typologists, most notably August Wilhelm Schlegel (1767–1845) and Wilhelm von Humboldt (1767–1835), elaborated on his bipartite classification, Friedrich Schlegel, alluding to the ultimate goal of typological classification, made a bold claim that the opposition between *Sprachen durch Flexion* and *Sprachen durch Affixa* represents the two main categories of language, all other cases being mere modifications and variants of these.

The typological studies of the early nineteenth century are also known as morphological typology, since the classificatory basis was the morphological structure of words. A beginning linguistics textbook typically introduces four types of language from this early endeavor: (1) inflectional (or fusional) type: relational meaning is expressed by internal modification of the lexical base such that component parts are not easily isolable (e.g., Indo-European languages, English *sing*:*sang*:*sung*); (2) agglutinative type: words consist of easily segmentable parts, each indicating a distinct grammatical meaning (e.g., Turkish *ev-ler-im-de* house-PL-1SG.POSS-LOC 'in my house'); (3) isolating type: words do not give overt expression of relational meaning or else do so by employing to the end the same kind of unit as is used for encoding lexical concepts (e.g., in Chinese the verb *gěi* 'to give' is used also as an indirect object marker); and (4) incorporating (or polysynthetic) type: nominal arguments (typically objects) and pronominal forms referring to them are incorporated in the verb form (e.g., Ainu *a-wakka-ta-re*1SG-water-draw-CAUS 'I make someone draw water').

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52009-1

Classical typology embodied system internal inconsistencies and had associated value judgments that caused its decline in the second half of the nineteenth century, when the study of genetically related languages was viewed as the only possible scientific comparative study of languages. Different languages were thought to represent different stages of the development of the languages and language families with the belief that the inflectional type, which fused distinct morphological information into single morphemes, represented the highest degree of linguistic sophistication. This assumption put classical Indo-European languages at the top of the evolutionary ladder and isolating languages of Asia, e.g., Chinese, at the bottom, contradicting the long history of the Chinese language and the advanced civilization associated with classical Chinese.

The quadripartite classification has shortcomings as a true classificatory scheme in that a language may have morphological characteristics of several types simultaneously. English, for example, shows an inflectional characteristic in some irregular forms (e.g., *bring*:*brought*, *man*:*men*), an agglutinative characteristic in regular verbal and nominal inflections (e.g., *walk*:*walked*, *book*:*books*), an isolating characteristic in certain modal expressions (e.g., *cannot walk*), and an incorporating feature in some compound forms (e.g., *to hand-knit a sweater*). Edward Sapir's multidimensional typology developed in his 1921 book *Language* (Sapir, 1921) was in part response to the need to accommodate gradient characterizations of linguistic types, as he saw that languages in their entirety could not be neatly pigeonholed into a given type, the matter being a question of tendency.

While classical typology saw the culmination in Sapir's highly elaborate classificatory scheme, his followers have not generally put it into practice. Indeed, the only place where classical, morphology-based typology has been seriously pursued is Prague, where Vladimir Skalička (1909–91), who recognized five types of languages (the four previous types plus the introflexive type), was a pillar of the so-called Prague School of Typology (see Sgall, 1995).

While morphological typology as formulated by the nineteenth-century grammarians is no longer considered to be adequate in meeting the ultimate goal of language typology, classical typology saw several developments of contemporary relevance. It is perhaps even fair to say that the followers of classical typology have contemplated most contemporary issues of language typology. For example, August Schleicher (1821–68) recognized the possible connections between morphological characteristics and the manner in which grammatical relations are expressed, thereby pointing to the current view that a language type is to be defined in terms of a combination of properties that exhibit correlative patterns. The evolutionary chain of isolating agglutination inflection envisioned earlier is now recast as a cyclic development, and such a model is integrated in the current study of grammaticalization (see Bybee, 1985; Hagège, 1988). The Humboldtian claim that the structure of a particular language reflects its speakers' *Weltanschauung* has stimulated a line of research on the relationship between language types and the speakers through the nineteenth century leading up to the so-called Sapir–Whorf hypothesis in the early twentieth century. This hypothesis claims a connection between the linguistic structure and the way the speakers perceive the outside world. As typological studies take on more cognitive outlook (see DeLancey, 1981), a reappraisal of the Humboldtian tradition may be in order. An interesting development along this line is the recent revival of interest in ethnopsychology and the development of what is dubbed as 'ethnosyntax' by Wierzbicka (1992) and others.

Modern Typology

A major difference between classical typology and modern typology, developed in the middle of the twentieth century, lies in its scope and methodology. Classical typology sought a global characterization of the entire language according to a small number of typological characteristics. This holistic approach has proved to be too ambitious, and modern typologists practice partial typology, where specific phenomena or individual grammatical constructions are studied. Methodologically, modern typology heavily relies on cross-linguistic distributional patterns. Implicational universals are drawn from the distribution of existing types and nonattested types.

Roman Jakobson (1896–1982) is generally regarded as the founding father of modern typology. In his seminal paper, Jakobson (1958/1971) recognized that typological analysis leads to the discovery of the dependency relation between two elements such that the presence of one element, X, implies the existence of another element, Y, in the same system (but not vice versa). For example, the parameters of voicing and aspiration in consonants yield the following four types of consonant system (illustrated with dentals): (1) /t/ and /d/; (2) /t/, /t^h/, and /d/; (3) /t/, /t^h/, /d/, and /d^h/; and (4) /t/, /d/, and /d^h/. Of these four logically possible types, only the first three are actually observed – no language has voiced aspirates in the absence of voiceless aspirates, i.e., the fourth system. From this, it is possible to formulate an implicational statement that the presence of voiced aspirates implies the presence of voiceless aspirates. This statement constitutes a universal constraint on human language if no language indeed violates the pattern implied by this statement – that no consonantal system can contain voiced aspirates in the absence of voiceless aspirates.

Developing Jakobson's insight in a systematic and overarching manner, Joseph H. Greenberg (1915–2000) has changed the whole perspective of linguistic typology, transforming it into a new method of universals research. Greenberg's (1966) study on word-order typology drew a large number of implicational universals encompassing both morphological and syntactic levels, and some transcending them. That languages differ in word order is a commonplace experience of those who are exposed to foreign languages. English is an SVO (Subject–Verb–Object) language, while Japanese is an SOV language. The less frequently observed VSO order is instantiated by Welsh. The impact of Greenberg's work was very strong because of the far-reaching predictions it made on the basis of this kind of simple, basic feature of language. For example, it has been shown that if a language has dominant VSO order, (1) it has prepositions (G's *Universal 3*), (2) the genitive follows the governing noun (G's *Universal 2*, originally formulated in terms of the presence of prepositions), (3) question particles that are specified in position by reference to a particular word in the sentence do

not occur (G's *Universal 10*), (4) it always puts interrogative words or phrases first in interrogative word questions (G's *Universal 16*), (5) an inflectional auxiliary precedes the main verb (G's *Universal 16*), and (6) adjectives come after the noun (G's *Universal 17*).

Greenberg's universals have the following two characteristics. They are implicational such that they are restricted universals. The universals cited above obtain only with regard to VSO languages, and they have nothing to say about those languages having a different word order. Secondly, Greenberg recognizes statistical universals or high cross-linguistic tendencies, which do not obtain absolutely. For example, Greenberg's *Universal 4* is formulated as follows: "With overwhelmingly greater than chance frequency, languages with normal SOV order are postpositional," which allows a language like Persian, which has SOV order with prepositions. Beside implicational and statistical universals, linguists, in general, recognize unrestricted universals, which are believed to obtain absolutely; for example, all languages have vowels and consonants, and all languages have nouns and verbs.

Implicational statements are also obtainable from hierarchies that grammatical categories exhibit. The most well-known grammatical hierarchy is that of grammatical relations formulated by Keenan and Comrie (1977): Subject > Direct Object > Indirect Object > Genitive > Oblique Object > Object of Comparison. This hierarchy, derived from the cross-linguistic relativization patterns, predicts, for example, that if a language allows relativization on an oblique object (i.e., an object of a preposition), then it also allows the same relativization strategy to apply to all those nominals holding the grammatical relations higher in the hierarchy than the oblique object.

Another hierarchy with far-reaching ramifications is the so-called animacy hierarchy: first/second person > third person > pronoun > human noun > animate noun > inanimate noun.

In a language such as the Australian language Dyirbal, where an agentive nominal of a transitive clause may receive either ergative or nominative marking – split-ergative marking – those high on the hierarchy tend to be marked nominative, while those low on the hierarchy tend to be marked ergative such that we can draw implicational statements to the effect that if an agentive nominal X in the hierarchy is marked nominative, all those higher in the hierarchy are also marked nominative. The animacy hierarchy is also at work in voice phenomena such that an agentive nominal high in the hierarchy tends to be expressed in subject position, i.e., in the active voice, while when a patient nominal is high in the hierarchy, passivization tends to occur. A corollary of these tendencies is that those nominals high in the hierarchy are less likely to be expressed overtly as an agentive phrase (as in the English *by* agentive phrase) in the passive clause.

Recent studies of prototype categories have revealed that grammatical categories and constructions form continua rather than exhibiting rigid category boundaries. For example, studies on transitivity have shown that the traditional binary distinction between intransitive and transitive verbs (or constructions) needs to be recast as a multivalued continuum (see Hopper and Thompson, 1980). A simpler and much coarser form of this continuum yields the following hierarchy: transitive > active intransitive > inactive intransitive, where active intransitive verbs/constructions are those expressing agentive activities (e.g., 'to dance') and inactive intransitive verbs simple nonagentive processes (e.g., 'to fall'). An implicational statement can be also derived from this hierarchy; for example, if a language permits passivization of an inactive intransitive, then it also permits active intransitives and transitive verbs to undergo passivization. Also, noun incorporation (see above) basically follows this hierarchy such that the object of a transitive clause is the easiest to incorporate, followed by the subject of an inactive intransitive clause, the subject of an active intransitive clause, and finally the subject of a transitive clause. Thus, if a language incorporates the subject of an active intransitive clause, then it is likely to incorporate the subject of an inactive intransitive clause and the object of a transitive clause.

Functional Typology

The term typology is used in reference to a theoretical and methodological approach that contrasts with other, especially Chomskyan generative, approaches. The Chomskyan generative approach is said to be formal in two senses. In one sense, generative grammar is formal in dealing with the "abstract formal skeleton" (Chomsky, 1975, p. 55) of syntactic structures as an autonomous system independent of semantic or functional factors. In another sense, generative grammar is formal in that its explanations are in terms of the system internal formal categories (e.g., noun phrases, verb phrases) and structural relations. The typological approach sharply contrasts with these two characteristics of generative grammar. Its basic orientation is functional in that it assumes that the central function of language is to represent cognition and to communicate experience and thought. The task of typology is to determine the range of variation that language permits in achieving this central function. In this framework, a language is seen as a problem-solving system: how languages conceptualize a given cognitive domain and express the concepts by linguistic means (see Seiler, 1995). Studies dealing with specific constructions such as causative and possessive constructions thus start out with the formulation of the concepts or the cognitive domains to be typed in terms of the correlations between grammatical form and semantic function (see Shibatani, 1976; Seiler, 1995). This cognitive-functional stance has a long and venerable history linking the current works with Sapir's and ultimately with the Humboldtian conception of language as an '*enérgeia*' (a creative activity) rather than an '*érgon*' (a product).

The term 'functional typology' is used in recent years in order to underscore the functional orientation countenanced by the current typological research. This approach also differs from generative grammar in its recourse to external explanations. Explanations for cross-linguistic patterns of linguistic structure are sought in functional motivations such as iconicity – preference for the structure of language to reflect and the conceptual structure in a parallel manner (see Haiman, 1985). Haiman has shown that conceptual distance is reflected in grammatical distance. Thus, inalienable possession, which involves an inseparable or a closely connected whole-part relation, is expressed by a more tightly integrated form than

alienable possession; for example, *ji syim* 'my arm' versus *ji bi nggwe* (my of house) 'my house' (Abun; West Papuan). Similarly, in causative expressions, shorter forms tend to express direct causation and the longer forms indirect causation, e.g., *kill* versus *cause to die*. In recent years, however, these iconicity-based explanations have been challenged and alternative usage-based explanations have been explored. These efforts are informed of some earlier observations on economically motivated tendencies such as Zipf's: "the length of a word tends to bear an inverse relationship to its relative frequency," "the degree of distinctness of meaning seem[s] to bear an inverse relationship to F[requency] and C[rystalization] [of the configuration]" (Zipf, 1935; see also Haspelmath, 2008).

Another line of research along the functional typological premise has been developed by Hawkins and his associates in which processing mechanisms are invoked as an explanation for observed linguistic patterns (see, e.g., Hawkins, 1990; Hawkins and Cutler, 1988).

Typology and Language Change

The importance of typology to one of the major concerns of historical linguistics, namely reconstruction of protolanguages, has long been demonstrated. The basic idea here is that where a reconstruction conflicts with the known typological facts, there is a *prima facie* reason to suspect its validity. The most celebrated phonological example of this use of typology as a control on reconstruction is concerned with the Proto-Indo-European consonant system. The standard reconstruction posited a threefold system of voiced and aspirated consonants (illustrated with dentals /t/, /d/, /d^h/). However, Jakobson (1958/1971) noted that typological investigation revealed that no language would contain /d^h/ in the absence of the voiceless counterpart /t^h/, casting doubt on the validity of the Proto-Indo-European system reached by the standard reconstruction. This has led to either reinstating the neogrammarians' earlier four-point stop system of /t/, /t^h/, /d/, /d^h/, or developing alternative hypotheses. The so-called glottalic theory, which replaces the traditionally reconstructed voiced stops with ejectives, has also been informed of typological results. Phonological systems comprising a voiceless, a glottalized, and an aspirated series (/t/, /t^ʔ/, /t^h/) conform to synchronic typological findings, but the system arrived at by the conventional reconstruction does not (see Gamkrelidze and Ivanov, 1973).

The move to bring typology to the heart of diachronic linguistics, namely linguistic change itself, has been spearheaded by Greenberg (1969, 1995), who advocates the dynamicization of a synchronic typology. Greenberg offers what he calls the 'state-process model,' which views attested language types as possible stages through which languages can pass and nonattested language types as impossible stages into which a language can change. In other words, just as synchronic typology puts constraints on language types, constraints on typological change can be viewed as limitations on language change.

The connection between synchronic typology and possible change can be illustrated by the typology of number categories in the noun. It has been shown that the category of dual is only found in a system having a singular–plural distinction – no language has a singular–dual system or a plural–dual system. When a language with no number distinction develops a number system, it involves a singular–plural distinction; no language develops a system with a tripartite singular–dual–plural distinction without going through a stage in which a singular–plural distinction has been established. In this way, diachronic typology seeks to identify allowable and non-allowable transition from one state to another so as to determine possible paths of language change.

In the Greenbergian diachronic typology, typological states and transitions between states are characterized by two logically independent factors – stability and frequency. Stability represents a probability that a language, which is in a particular state, will exit from that state, while frequency is the likelihood that a language will enter a particular state. For example, a state of having nasal vowels is characterized as having high frequency but low stability, because a vowel frequently acquires the nasality feature from an adjoining nasal consonant, but once a system acquires nasal vowels, it tends to retain them. The dimensions of frequency and stability of typological states render the state-process model a probabilistic one, which countenances the gradualness of the transition from one language state to the next. In this model, synchronic exceptions are accounted for as transitional states arising from gradual diachronic process of change from one state to another.

The two main concerns of diachronic typology – gradualness of historical change and its directionality – have received focused attention in the recent developments in grammaticalization research (see Bybee, 1985; Heine et al., 1991; Hopper and Traugott, 1994; Lehmann, 1982). Grammaticalization refers to the process by which lexical items come to take on grammatical functions such as marking of tense, aspect, grammatical relations, definiteness, modality, etc. In Chinese, the verb *gěi* 'to give' is used as an indirect object marker, and the verb *iru* 'to be/to exist' in Japanese has developed an aspectual usage of indicating an ongoing activity, the progressive aspect.

Grammaticalization typically involves a synchronized change in several different grammatical dimensions. As a lexical item gets grammaticalized, it tends to undergo phonological reduction, which in turn renders the form less independent, downgrading it to a morphologically dependent status, as in the case of enclitics and affixes. Semantically, a lexical item gradually loses its original referential meaning and acquires such relational meanings as those previously noted as well as subjective and interpersonal meanings. As in the case of the Chinese verb *gěi* and the Japanese verb *iru*, grammaticalization is a gradual change such that these forms coexist as verbs along with the newly developed grammatical functions. The three main concerns of grammaticalization theory are as follows:

1. the relationship between the input and the output of grammaticalization – What kind of lexical items give rise to what kind of grammatical functions?,
2. the directionality of change – Is the change unidirectional from concrete to abstract?, and
3. the gradualness of change – Is grammaticalization a gradual change or can it happen instantaneously?

The gradual aspect of historical change brought to the fore by diachronic typology and grammaticalization research has an important implication to the matter of definition as well as the synchronic characterization of a language. Many phenomena are in transition from one state to another, and as such they are not amenable to categorical definitions. For example, whether Chinese has prepositions or not is not an easy question to answer, as forms such as the indirect object maker evolving from the verb *gěi* 'to give' can be construed either as verbs or prepositions. The existence of transitional phases of this kind calls into question the traditional distinction between synchronic linguistics and diachronic linguistics. Dynamicization of a synchronic description is the next logical step that diachronic typology suggests.

Typological Differences in Clausal Organization

As described in Section Typology and Language Change, modern typology typically examines specific domains or individual grammatical constructions in order to ascertain possible variation in human language. This leaning toward partial typology stems from the difficulty encountered in attempting to typologically characterize languages in their entirety. Despite this, there is a lingering sense among typologists that a holistic characterization of a language is a desideratum. Georg von der Gabelentz most eloquently expressed this feeling at the beginning of the twentieth century:

> But what an achievement would it be were we to be able to confront a language and say to it: "you have such and such a specific property and hence also such and such further properties and such and such an overall character"—were we able, as daring botanists have indeed tried, to construct the entire lime tree from its leaf.
>
> Gabelentz, 1901, p. 481

Whether or not the ideal entertained by Gabelentz can ever be reached remains to be seen. However, one area that merits further investigation is the differences that languages show in the organization of clause elements. In compensation for the emphasis on methodological matters in the preceding *exposé*, the following allows a glimpse of what actual typological investigation or comparison of languages in general involves.

In expressing a transitive situation involving an agent and a patient participant, languages typically distinguish these in some way so that who is acting on whom is made clear. English, for example, achieves this by using different pronominal forms, e.g., 'He hit him.' In the case of intransitive clauses, its sole nominal argument (S) can be assimilated either to the form of an agentive nominal (A) or to that of a patient nominal (P). English assimilates it to the nominal form of A – 'He fell, He ran/*Him fell, *Him ran.' A clause that treats S and A alike and distinguishes P from these is said to display the nominative-accusative coding pattern ($S = A \neq P$), and the languages possessing such clauses predominantly are called nominative-accusative-type languages.

Some languages organize clauses differently from the nominative-accusative pattern. Many Australian Aboriginal languages follow the absolutive-ergative pattern, whereby S is identified with the P nominal, a transitive clause, while distinguishing A from these, i.e., the $S = P \neq A$ pattern. Clauses may be organized in yet another way. The American Indian language Lakhota, for example, splits S nominals into an agent-like category (S_a) and a patient-like category (S_p), yielding the coding pattern, known as active-type: $S_a = A \neq P = S_p$.

All of these languages have a single type of dominant transitive clause, where the coding of A and P is fixed. Some languages have more than one type of transitive clause, making a unique comparison of intransitive clauses with transitive clauses problematic. Philippine languages are such languages, where a simple transitive clause comes in two variant forms. Cebuano, for example, renders the sentence 'Juan read the book' in two ways: *Ni-basa si Juan sa libro* (AF-read TOP Juan the book) and *Gi-basa ang libro ni Juan* (GF-read TOP book ACT Juan). (AF = actor-focus marking; GF = goal-focus marking; TOP = Topic marker; and ACT = Actor marker.) That is, either A or P can be coded as what is called Topic (marked *si* for proper names and *ang* for common nouns) of a transitive clause. The S nominal of an intransitive clause is coded as a Topic as in *Ni-dagan si Juan* (AF-run TOP Juan) 'Juan ran.' The focus marking in the verb indicates what semantic role is being coded as Topic such that the prefix *ni-* in Cebuano indexes an agentive Topic, and *gi-* a patient Topic. This applies to both transitive and intransitive clauses such that an intransitive clause with a patient S Topic would trigger *gi-* marking; *Gi-kapoy si Juan* (GF-tired TOP Juan) 'Juan is tired.' This split treatment of S Topic marking in the verb is reminiscent of the active-type coding pattern. However, Philippine languages are not active-type languages in that the nominal marking is consistent for S – it is always realized as *si*/*ang*-marked Topic – and that there are two competing forms of a transitive clause (see Shibatani (1985) on the Philippine voice system).

The four types of coding pattern examined have important implications for some basic grammatical categories. First, the notion of Subject is problematic in those clause types displaying coding patterns other than the nominative-accusative pattern. Subject, as found in European languages, refers to the category obtained from the $S = A$ grouping in the nominative-accusative pattern. It is a category deriving from the assimilation of S to A, and accordingly is agent-based.

Morphological identification of S and P obtains in an ergative-type language. A long-standing question in typology is whether this grouping of S and P should be identified as Subject. One obvious problem with this move is that whereas Subject is an agent-based category, the $S = P$ grouping is a patient-based category, since it obtains by assimilating S to P. Thus, a conservative view is that the $S = P$ grouping forms a category distinct from Subject. Since S and P typically involve zero marking, the term Absolutive suggests itself as the label for this category.

In active-type languages, there is no unique identification between the totality of S and A or P, and therefore, neither Subject nor Absolutive category obtains. In Philippine linguistics, Topic is often likened to Subject, but since it is based on neither A nor P – either can be Topic, and S can be identified with either kind of Topic – it is neither an agent-based nor a patient-based category.

While different clausal types of the world's languages may display grammatical relations resembling Subject, they are not entirely identical. Subject is agent-based, whereas Absolutive is patient-based. Philippine Topic is neutral in its alignment with the semantic roles. These different grammatical relations, however, can be identified at a functional level in that they are the essential relations that a nominal must bear in clause formation. That is, Subject, Absolutive, and Topic are an indispensable nominal category in a clause over which a verb predicates. Predication will not be complete without a nominal category about which the verb says something. The primary status of these grammatical relations is reflected in the primacy they enjoy in such grammatical processes as relativization and focusing. Subject, Absolutive, and Topic, in other words, can be identified as a primary relation at the functional level, despite the differences at the substantive level.

The differences in grammatical relations have some additional implications. Firstly, it predicts that those languages that do not have the Subject category do not show the active–passive voice opposition. Active voice (as expressed by 'John hit Bill') is defined in terms of the alignment of A and Subject and of P and Object, while passive voice entails the alignment of P and Subject and of A with Oblique (a peripheral, typically optional syntactic element), as in 'Bill was hit by John.' From this, it is obvious that languages without the Subject category cannot have the active–passive opposition in exactly the same way as in nominative-accusative-type languages. In place of the active–passive opposition, ergative languages often display ergative-antipassive voice alternation, characterized by the realignment of A from Ergative to Absolutive and of P from Absolutive to Oblique. Some ergative languages, in addition, display an analogue of the passive construction aligning P with Absolutive and A with Oblique.

In both active–passive and ergative-antipassive oppositions, there is a basic voice construction associated with the basic form of the verb. In the former, the nominative-accusative active form is the basic voice, and in the latter, the form coded in the absolutive-ergative pattern is basic. In this regard, the active and the ergative voice are a primary voice category and are functionally equivalent. Derived voice forms, the passive and the antipassive, typically contain morphologically derived verb forms, and they are used far less frequently than the unmarked, basic voice forms. Philippine-type languages, in contrast, have no unmarked voice category – the alignment of Topic with A or P is equally marked in the verb. A characteristic of the fluid-voice system of this kind is that both A-Topic form and P-Topic form are used with equal facility such that there is no lopsided distribution of voice forms as in the other two systems discussed previously. In contradistinction to these types of languages, active-type languages are known to lack voice opposition of the kind discussed here. The three voice mechanisms studied – the active–passive system, the ergative-antipassive system, and the fluid-voice system of Philippine languages – are different in their substance. Yet, they are comparable at the functional level in that they all involve realignment of a primary argument.

Languages can differ with respect to the nature of grammatical relations and voice mechanisms depending on the way clauses are organized. Besides these, cross-linguistic differences in other grammatical phenomena have been reported, some of which may be attributable to the typological differences outlined here. The question of whether these differences have profound implications for the overall organization of grammar aside, it is becoming increasingly clear that languages are likely to differ at the level of grammatical organization far more greatly than was believed in the latter half of the twentieth century, when categories and construction types were transferred from one language to another rather carelessly on the basis of partial similarity. Once a clear distinction is made between the substantive aspects of categories and constructions and their functional status within each language, languages can be profitably compared in terms of the functional equivalence or similarity even if they define and organize grammatical elements in quite different ways.

Abstract

The development of the history of linguistics as a serious scholarly activity has its own long history that can be traced in the textbooks from mid-nineteenth to the mid-twentieth century. It is, however, only since the 1970s that the history of linguistics/language sciences has developed into a subdiscipline of linguistics in general and a subject to which the beginning level students of the discipline would be introduced as part and parcel of their formal education. In this article four main approaches to writing the history of linguistics are distinguished and discussed: (1), the summing up of the history, which presents the results of established procedures within the discipline; (2) the revolutionary history intended as propaganda for a new paradigm; (3), the non-partisan constructive history, which emphasizes continuity and progress in the discipline; and (4) the historiography of linguistics, a relatively new approach that seeks to treat the history of linguistics as a scholarly endeavor in its own right which may also inform work in other linguistic subdisciplines.

A discipline comes of age when it seriously contemplates its own past. The History of Linguistics (HoL) – now frequently referred to as 'History of the Language Sciences' – is an attempt to steer away from a narrow view of 'linguistic science.' HoL as a bona fide subject of academic research (in which doctoral dissertations can be written, for instance) began to develop only during the late 1960s, although such work had previously been done in departments of Germanic, Romance, or Slavic where such research surveys were at times undertaken to delineate the course a particular field had taken or the evolution of a specific idea or research project. It has been customary, at least since the 1880s, to add an historical introduction to textbooks in linguistics, but usually the intent has been to show the significance of recent advances in the field compared with previous endeavors. During the 1960s, following various claims made by Noam Chomsky that his own theories had little to do with the pursuits of his immediate predecessors and contemporaries, but instead followed quite different traditions such as those of the Port Royal Grammar and of Wilhelm von Humboldt, the bulk of the dissertations written in HoL were devoted to just these areas of interest, at times seriously distorting the true intent and purpose of these earlier authors. Only from the 1970s onwards, following the creation of the first journal for this particular field of interest in 1973, *Historiographia Linguistica*, and the associated monograph series united under the umbrella titled 'Amsterdam Studies in the Theory and History of Linguistic Science,' did serious work begin to emerge that challenged this *pro-domo* type of history writing. These and other organized activities (which we discuss in the subsequent sections) led to much more recent field of study, now generally referred to as Historiography of Linguistics (see Koerner, 2006 for an extended discussion) or 'Linguistic Historiography' for short, an approach to HoL which is conscious of methodological and epistemological requirements in adequate history writing in linguistics as in any science. (Most of the contributions to the two-volume *Historiography of Linguistics* published in 1975 under the main editorship of Thomas A. Sebeok were little else but surveys of previous scholarship; 'historiography' there being used in the old sense of the term; the volume edited by Parret in 1976 followed largely the Chomskyan manner of misappropriating the history of linguistics for 'political' purposes.)

It is true that we could perhaps by now speak of a 200-year tradition of linguistic history writing, perhaps beginning with François Thurot's (1768–1832) 1796 *Tableau des progrès de la science grammaticale* (cf Andresen, 1978), although several earlier works have been cited, for instance Elias Caspar Reichard's (1714–1791) *Versuch einer Historie der deutschen Sprachkunst* of 1747 (cf Koerner, 1978a: vi, for references to other eighteenth-century works). However, as the record suggests (Koerner, 1978a: pp. 1–4), it is only from the late 1860s onwards that a more thorough type of treatment of HoL emerges of which Theodor Benfey's (1809–81) monumental *Geschichte der Sprachwissenschaft* of 1869 may be regarded as the most outstanding example. It had been preceded by Heymann Steinthal's (1823–99) work of 1863, which sought to supersede Laurenz Lersch's (1811–49) three-volume *Die Sprachphilosophie der Alten* (1838–41), but which dealt only with the contributions of Greece and Rome to linguistic thought. Benfey's history of linguistics was followed by other influential works such as Raumer (1870), Delbrück (1882[1880]), Bursian (1883), which, however, were more limited in scope. The same could be said of books by scholars such as Thomsen (1902; German transl., 1927), Delbrück (1904), Trabalza (1908), Jellinek (1913), Pedersen (1916; English transl, 1983), Pedersen (1924; English transl., 1931), Dràganu (1945; Italian transl., 1970), or Robins (1951) from the first half of the twentieth century. (For detailed descriptions of these books, see Koerner, 1978a.)

New endeavors and, at times, more insightful studies in HoL appeared in the 1960s, perhaps beginning with Paul Diderichsen's (1905–64) work on his compatriot Raskof 1960 (German transl., 1976). It was followed by works such as Ivić (1963; English transl., 1965), Leroy (1963; English transl., 1967), Tagliavini (1963), Malmberg (1964; French transl., 1959), Lepschy (1965; English transl., 1970), Mounin (1967), Robins (1967), Coseriu (1969, 1972 see now Coseriu, 2003), Helbig (1970), Szemerényi (1971), and other thematically restricted books (cf Koerner 1978a for details, Jankowsky (1972), and others (see Koerner, 1978a for a full

list). Yet most of them relied uncritically on earlier accounts and rarely ventured into questions of historiographical method or touched upon matters concerning the philosophy of science, except perhaps for a fashionable nod to Kuhn's *Structure of Scientific Revolutions* of 1962.

Looking back on the past 140 or so years of history writing in linguistics, it is possible to discern three distinct types, each associated with particular motives for engaging in such activity and each occurring at specific periods in the development of the discipline. A fourth type (argued for in, e.g., Koerner, 1976) has begun developing only in more recent years. Detailed description of each of these follows.

1. First, there is the type of history written at a time when a particular generation or an individual representing the ideas, beliefs, and commitments of his or her generation to a significant extent is convinced that a desired goal has been reached and that subsequent work in the field will mainly be concerned with what Thomas S. Kuhn has referred to as 'mopping-up operations.' These accounts assumed that the theoretical framework had been sufficiently mapped out for the ordinary member of the scientific community to conduct his or her investigations and that there was no longer any need for a revision of the methodology or the approach to the subject matter under analysis; they were summing up histories that viewed the evolution of the field as growing in a more or less unilinear fashion.

This idea of or motive for writing such a history seems to be best expressed in Benfey's voluminous *Geschichte der Sprachwissenschaft und orientalischen Philologie* (1869), appearing one year after Schleicher's untimely death, and also by Raumer's *Geschichte der germanischen Philologie* (1870). It is difficult today to recreate the atmosphere of the late 1860s even if we limit ourselves to linguistic matters abstracting from external, for example, socio-political, currents: histories available today supply us with little, if any, information on this pre-neogrammarian period. Suffice it to recall for the present purpose that the works of Bopp, Rask, Grimm, and others had been significantly synthesized and methodologically developed by the generation of Georg Curtius (1820–85) and, especially, August Schleicher (1823–68), to the extent that one might speak of a 'paradigm' change having taken place at that time, of which the neogrammarian tenets of historical linguistic research associated with the names of their former students, notably Karl Brugmann (1849–1919) and August Leskien (1840–1916), were the logical, if somewhat overstated, outcome.

A similar observation about the motives of history writing, it would seem, could be made about Holger Pedersen's (1867–1953) 1924 history of the achievements of nineteenth-century Indo-Europeanists, which was preceded by a similar and somewhat shorter account of his first published work in 1916, the year of the completion of the second edition of Brugmann and Delbrück's *Grundriss*, as well as the appearance of Saussure's *Cours de linguistique générale*. The feeling of the need of such a summing-up history is expressed more clearly, perhaps, in Wilhelm Streitberg's (1865–1925) voluminous undertaking, entitled *Geschichte der indogermanischen Sprachwissenschaft seit ihrer Begründung durch Franz Bopp*. However, this is in fact more of a résumé of the work accomplished in the various branches of Indo-European philology by that time than a regular HoL (cf Koerner, 1978a: 16–17, for details). Begun in 1916, the enterprise was abandoned after 1936.

After World War II, it appears that the histories by Malmberg (1964), Ivić (1965), Leroy (1963), and others fulfilled a similar function of summing up previous attainments in linguistic science. This time the focus of attention was the post-1916 period in the history of linguistics, following the success story of Saussure's *Cours*, with its perceived emphasis on a non-historical approach to language. The neogrammarian framework of linguistic research was propounded in the histories of Pedersen, the organizational efforts of Streitberg from 1916 onwards, and other less influential books – and one may add that Pedersen, a second-generation Neogrammarian, reflects the alleged 'data-orientation' of that school much more emphatically than the original group of scholars (note that neither Delbrück's *Einleitung* nor Paul's *Prinzipien* are even mentioned in his 300-page study of 1924). Only in recent years (Jankowsky, 1972; Einhauser, 1990) have the Neogrammarians received a more adequate treatment. By the same token, the histories by Malmberg, Ivić, Leroy, and other similarly slanted studies of the 1960s put forward particular post-Saussurean trends as the most significant achievements of the discipline to date, whether Copenhagen-type, Praguean, or Bloomfieldian. Their endeavor, like that of Benfey, Raumer, Pedersen, Streitberg, and others from an earlier stage in the development of linguistics, was to a large extent the presentation of a framework of research in which they themselves had been brought up, and, concomitantly, an attempt to maintain the strength and impact of the structuralist mode of thought.

2. The second type of history-writing activity may be characterized by the intention on the part of an individual usually in his thirties (not late forties or above, as is generally the case with the first type), again representing a particular group, to launch a campaign opposing previously cherished views and still prevailing doctrines. Thus in contrast to Benfey (1869), for example, Berthold Delbrück's (1842–1922) 1880 *Einleitung* served, together with Paul's *Prinzipien* of the same year, as the mouthpiece of a new generation of scholars eager to demonstrate that their achievements significantly surpassed previous attainments in the field, and that their theories rightfully replaced those taught by the preceding generation of linguists. The claim in favor of discontinuity is what characterizes this type of activity, and Delbrück's book is a prime example of this endeavor. Typically, Schleicher was depicted by Delbrück as representing the conclusion of the phase of comparative-historical grammar inaugurated by Franz Bopp in 1816, and the *Junggrammatiker*, with whom he associated himself early in his career (soon after he had received Schleicher's chair at the University of Jena in 1873), as marking a decisive new turn in the field.

No comparable history of linguistics was written in the 1930s and 1940s with regard to structuralism, but a look into Bloomfield's *Language* (1933) or Gray's *Foundations of Language* (1939) clearly suggests that the chapters devoted to HoL were an attempt to redress the development of the

discipline and to document the superiority of the structuralist approach to any other theory or method hitherto put forward. This endeavor to prove earlier views to be utterly insufficient and inadequate has by no means been abandoned by adherents of the prevailing modes of linguistic thinking of today. On the contrary, it can easily be shown that their advocates have been eager not only to revive an interest in the history of linguistics itself but also to rewrite it to an extent that the ideas of the generation immediately preceding the present one appear the least worthy of attention. As a matter of fact, what C.F. Voegelin felicitously termed the 'eclipsing stance' that transformational-generative grammar had embarked on was best illustrated by Noam Chomsky himself, for instance in his 1962 lecture at the Ninth International Congress of Linguists held in Cambridge, MA (Chomsky, 1964). Soon thereafter, a number of his followers ardently engaged themselves in writing their particular view of history; compare the articles by Dingwall (1963), Bach (1965), or Bierwisch (1966). More recently, Frederick Newmeyer has published a book that constitutes the best example to date of this *pro domo*, Whiggish type of history writing. It selects and reinterprets past linguistic research in an attempt to prove his view that linguistics was made a science only in 1955 or in 1957, and by Chomsky, and that previous work was totally inadequate, barring a few minor incidental insights foreshadowing the 'revolution' in the field (cf Koerner, 1983; for a critical assessment of this kind of activity). Newmeyer's *Linguistics in America* (1980) appeared exactly 100 years after Delbrück's *Einleitung*, and the parallels between their authors are striking indeed: both were less than 40 when they wrote their books; both were primarily interested in syntax, not phonology, and neither had done his doctorate at the respective centers of the schools whose success story they depicted.

While Type I history writing may appear more benign as it seems to represent matter-of-fact accounts (although one should not be too sure about this), Type II HoL can best be described as propagandistic in nature; the most successful example of this type is Chomsky's 1966 *Cartesian Linguistics*. This book presents the author's views regarding the ancestry of his own theories so brilliantly that many a young students of language were carried away by this new vision of history. Today, we still find a lot of useful information in the Type I histories of the field despite their biases and shortcomings (see, e.g., Hoenigswald, 1986; Koerner, 1989); Type II histories, in contrast, although written much more recently, are already dated. It appears that, once their propagandistic purpose has been satisfied in proselytizing for the new ideology, the remainder rapidly loses its initial interest and apparent informational worth.

3. There is a third type of HoL which is intended neither to advocate a particular framework or 'paradigm' nor to attempt to provide an argument in favor of a scientific revolution within the discipline. This type may occur at any time in the development of a particular field of research since its ultimate intent is less partisan than in the other two instances and often more holistic in attitude, although the motivation behind the work may be fairly personal. To my mind, the best example is Arens' 1955 *Sprachwissenschaft*, in which an attempt was made to delineate the development of western linguistic thought from the early discussions of the Greeks about the nature of language to contemporary linguistic work, certainly with a view to indicating not only that our discipline has come a long way to gain those insights we now cherish and the methods we have developed, but also that we all have built, knowingly or not, on the findings of previous generations of linguists, and that we owe much more to these scholars than we might ever become fully aware of.

While this Type III manner of presenting the HoL might well have been the result of a very personal choice, it appears that it expressed the endeavor of a whole generation of scholars, namely, the rebuilding of a discipline after its almost total destruction through a world war. Taken in this way, Pedersen's 1931 book may well be included in the third category in that it sought to reestablish a linguistic tradition which in his belief could continue to serve as a sound basis for subsequent work in the field.

Undoubtedly, other, often nonlinguistic, motives played a role in presenting the history of the discipline in one way or another. Thus, it should be recalled that particular socioeconomic conditions, historical events, or political situations have often had a considerable influence on the motivation of writing the history of a particular discipline or the acceptance of a seemingly new theoretical framework of research or mode of thought – and in this respect histories of linguistics have failed to increase our awareness of the impact of matters or events outside the field. The works of Benfey and Raumer, for instance, were highly motivated by the rise of German nationalism and the aspiration to national unity if not superiority. Similarly, Malkiel (1968: 557) rightly observed that the success of Saussure's *Cours* "cannot be properly measured without some allowance for the feelings of that time: The acceptance of the leadership of a French-Swiss genius connoted for many Westerners then opposed to Germany a strongly desired, rationalized escape from the world of Brugmann, Leskien, Osthoff, and Paul."

4. Despite the respect scholars may have for works of the third type, in particular Arens' *Problemgeschichte*, some have felt a need for yet a fourth type of history writing (e.g., Koerner, 1976; Simone, 1975), namely the presentation of our linguistic past as an integral part of the discipline itself and, at the same time, as an activity founded on well-defined principles that can rival, in terms of soundness of method and rigor of application, those of linguistics itself. This fourth type, now usually referred to as 'linguistic historiography' or, more properly, the *historiography of linguistics* holds that the HoL should not merely be subservient to the discipline, but should assume a function comparable to that of the history of science for the natural scientist. In short, while recognizing the important distinction between chronicle and history which Benedetto Croce is credited with, recent contributors to HoL have gone a step further by distinguishing between history and historiography. This is partly an attempt to make clear a departure from previous endeavors in the field, which only too often tended to be partisan histories, if not what Henry Butterfield termed 'Whig-histories,' and partly because previous histories did

not provide a usable guide for the adequate treatment of past developments in the history of the language sciences, and thus failed to provide a better understanding of where current theories may lead us to.

Another indication of the History of Linguistics having become a mature field of scholarly endeavor is its professionalization. In 1978, the first International Conference on the History of the Language Sciences (ICHoLS) was held in Ottawa, Canada, the same year in which the Société d'Histoire et d'Épistémologie des Sciences du Langage (S.H.E.S.L.) was founded in Paris. In 1984, the Henry Sweet Society for the History of Linguistic Ideas (HSS) was established in Oxford, and several similar international and regional societies have been launched since; for instance, the North American Association for the History of the Language Sciences (NAAHoLS) which was launched late in 1987. In the meantime further ICHoLS meetings have been held in 1981 (Lille, France), 1984 (Princeton, N.J.), 1987 (Trier, Germany), 1990 (Galway, Ireland), 1993 (Washington, D.C.), 1996 (Oxford), 1999 (Paris), 2001 (São Paulo, Brazil), 2004 (Urbana Champaign, USA), 2008 (Potsdam, Gemany), and 2011 (St. Petersburg, Russia), with the 13th such International Conference scheduled to take place in 2014 (Vila Real, Portugal). In addition to *Historiographia Linguistica*, a second journal with much less focused goals, entitled 'Histoire – Épistémologie – Langage,' was established in Paris in 1979, and more recently in 1991, a third journal, *Beiträge zur Geschichte der Sprachwissenschaft*, was launched in Münster, Germany. Subsequently, scholarly societies devoted to HoL were founded in a number of other countries, notably the Sociedad Española de Historiographia Linguistica of Madrid.

Although a couple of scholars were courageous enough to attempt an account of the development of linguistics from the Ancients to modern times (Swiggers, 1997; Allan, 2009), by the mid-1990s it became obvious that the history of linguistics – and not only the Western tradition – could no longer be adequately treated by individual scholars, but that international collaboration was required. This was recognized by Lepschy (1990–98), which treated only selected periods, with the concluding volume covering nineteenth-century historical-comparative philology. Selective accounts of HoL are increasingly focused on specific linguistic subdisciplines, for example, semantics (Gordon, 1982; Nerlich, 1992), pragmatics (Nerlich and Clarke, 1996), and syntax (Forsgren, 1992), and on specific theoretical stances (e.g., Matthews, 1993, 2001). The first more successful attempt to account for the diversity of linguistic traditions and research interests was Koerner and Asher (1995) culminating in a three-tome undertaking of close to 3000 pages (Auroux et al., 2000–2006). In short, if the professionalization of the subject is any guide, the History of Linguistics has become a widely recognized and practiced field of scholarly research (cf also Allan, 2013).

Linguistics: Incorporation

Elke Nowak, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Incorporation is a phenomenon whereby what might be expected to appear as a separate word in a sentence in fact shows up as part of the predicate: when incorporated, a noun becomes part of the incorporating verb and specifies it. The special nature of incorporation has been known to linguists for some time. Although it is known that the phenomenon is not restricted to indigenous American languages, it was first and foremost with respect to these languages that incorporation was, and still is, being discussed. In the following, a three-way distinction between noun incorporation, argument incorporation, and grammatical incorporation as a continuum of morphological complexity is introduced.

Introduction

Incorporation is a phenomenon whereby what might be expected to appear as a separate word in a sentence in fact shows up as part of the predicate: when incorporated, a noun becomes part of the incorporating verb and specifies it. The special nature of incorporation has been known to linguists for some time. Although it is known that the phenomenon is not restricted to indigenous American languages, it was first and foremost with respect to these languages that incorporation was, and still is, being discussed. In the following, a three-way distinction between noun incorporation, argument incorporation, and grammatical incorporation as a continuum of morphological complexity is introduced.

Traditionally, noun incorporation is understood as a choice of whether the direct object argument of a verb is retained on the syntactic level or not. In addition to it, argument incorporation refers to the realization of the verb's arguments, i.e., subject and direct object, exclusively on the morphological level, i.e., verb internally. In that case, no arguments can be identified in syntax, since the basic grammatical relations exclusively materialize on the word level. Going a step further, functional items may be incorporated as well. In languages which exhibit grammatical incorporation, various other kinds of grammatical relations, e.g., passive, causative, relative and contact clauses, complementation, adverbial and prepositional information, are realized verb internally, i.e., syntax is largely replaced by morphological complexity. The term 'incorporation' will be used for all three types, regardless of whether the involved items are independent lexical units, i.e., words, or bound morphemes. Such a distinction becomes instrumental for differentiating the different types of incorporation.

Noun Incorporation

Since Kroeber (1909, p. 569) and Sapir (1989/1911, p. 254), noun incorporation has been characterized as stem combination, i.e., the combination of independent lexical items into a complex verb. The most basic manifestation of incorporation brings about the detransitivization of a transitive expression: the direct object argument of the verb is incorporated, as shown in ex. (1a) and (1b). The verb stem determines the newly built complex word categorically, while the incorporated noun loses its categorical features, as well as any grammatical markings such as case or plural, see ex. (3b) below. Nouns do not incorporate as syntactic arguments, but as stems, specifying the incorporating verb.

(1) (a) Mohawk

/wa?kyvtho?	oji:ja?/	'I planted a flower'
wa?	aorist modal prefix	
-k-	1st person singular agent	
- yvtho?	'plant	

(b) Mohawk

/wa?kji?jayvtho?/	'I flower-planted'
-ji?ja:	'flower'

(Bonvillain, 1972, p. 21)

Although the most general features of the construction might at first suggest so, noun incorporation is more than just another variety of compounding. Conspicuously, languages featuring regular and productive compounding, such as German, frequently do not allow for incorporation (Nowak, 2011, pp. 233–235). Contrariwise, incorporating languages do not necessarily allow for compounding.

In many languages, noun incorporation is not a fully productive process, but restricted to certain types of nouns, most often related to the degree of animacy, or the language provides special sets of suppletive forms for incorporation. See, e.g., Allen et al., 1984 on Southern Tiwa; Mithun, 1984, pp. 863, 876, 877; 2001, pp. 44–47.

With respect to discourse and information structure, the incorporating process often entails a loss of referentiality of the incorporated noun and its being backgrounded as aforementioned information. From the perspective of the speaker, incorporation represents an option, since it offers an alternative way of expression, a strategy to decrease the informational content of a proposition or to bring about a focus shift when proceeding in discourse (cf Mithun, 1984, pp. 869ff. on Mohawk). Thus, the incorporated variant must always be seen in contrast to its non-incorporated counterpart. Being a matter of discourse and style, noun incorporation is expected to be a nonobligatory process. As has been pointed out frequently, it represents an elaborate register and, with bilingual speakers,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52035-2

characteristically is lost with decreasing fluency and competence (see, e.g., Mithun, 1984, p. 879ff.).

It is just this optionality, allowed for by the lexical independence of the constituents involved, which has motivated the interpretation of incorporation as a syntactic process, as a grammatical function-changing operation (Baker, 1988). Viewed from a syntactic point of view, the incorporated noun vacates its original place in the sentence as direct object. Yet it does not incorporate as argument of the verb, but as bare lexical item. Consequently, incorporation is understood as causing the loss of an argument position in syntax; the transitive expression becomes intransitive.

If at all possible, the incorporation of the external argument, i.e., the subject, typically is restricted to nonagentive noun phrases (Sapir, 1989/1911, pp. 252, 266; Mithun, 1984, p. 853; Gerdts, 1998, p. 87; Cook and Wilhelm, 1998).

(2) (a) Chukchee

nejə-k	ʔalʔal	təlgə-gʔi
hill-LOC	snow.ABS	thaw-3SG.S

(b) Chukchee

nejə-k	ʔələ = lgə-gʔi
hill-LOC	snow = thaw-3SG.S

'the snow thawed on the hill'
(Spencer, 1995, p. 451)

As has been discussed so far, in its weakest form, noun incorporation simply causes detransitivization, as in ex. (1a) and (1b). But many degrees of complexity are to be found. In its most dramatic version, phrasal constituency is dissolved and the constituents of the former noun phrase are distributed inside and outside the complex verb. As can be seen in ex. (3b), the head of the noun phrase, 'men,' is incorporated, while its modifiers remain in their syntactic, i.e., external position. This phenomenon is often referred to as 'external modification' or 'classifying incorporation.'

(3) (a) Southern Tiwa

Wisi	seuanin	bi-mū-ban
Two	man:pl	1sB-See-past

'I saw two men'

(b) Southern Tiwa

Wisi	bi-seuan- mū-ban
Two	1sB-man-see-past

'I saw two men'
(Allen et al., 1984, p. 295)

It must be kept in mind that it is exactly the distinction between syntax and morphology, and the interaction between these two levels, on which the specificity of noun incorporation rests.

Argument Incorporation

It is appropriate to distinguish noun incorporation from what was initially called 'pronominal incorporation' by Sapir. Contrary to what the term might suggest, usually no lexical pronoun is incorporated. The morphemes under consideration most often cannot even be reconstructed as historically independent forms, but are, and always were, bound morphemes, obligatory, and paradigmatically ordered (Sapir, 1989/1911, pp. 250–252). Following Evans (1999), it may also be assumed that their semantic properties are different from those of lexical pronouns, which play such an important part in syntax. The more recent term "pronominal argument" (Jelinek, 1984) draws on the relation to syntax again: the arguments of the verb are fully and exclusively expressed in form of bound morphemes, i.e., by morphological marking. 'Pronominal' refers to the fact that it is the indication of 'person,' often fused with other grammatical features such as number, which is expressed. But in fact, these markings do not replace a noun, as pronouns in European languages do. If noun incorporation offers a choice of expression to the speaker, argument incorporation does not. Since the arguments of the verb are expressed as bound morphemes joint to the verbal root or stem, no lexical arguments are necessary. Most often, a lexical manifestation/specification of the pronominal argument outside the verbal complex is highly marked and extraordinary. The way lexical content of third-person arguments is expressed differs widely from language to language, noun incorporation being one, as can be seen with ex. (4). The expression of grammatical relations is shifted from the syntactic level to the word level, as is illustrated by all examples to come. As opposed to noun incorporation, 'pronominal', i.e., morphological, arguments are not potential syntactic arguments, but represent the fundamental grammatical relations of the proposition. They must not be confused with inflection, which merely reflects the grammatical relations constituted on the syntactic level. In order to decide whether a person-marking morpheme has inflectional status or whether it actually represents the argument(s) of the verb, careful investigation is needed. To decide whether syntactic argument positions are available at all in a particular language, the application of test procedures identifying the status of syntactic constituents is helpful. Such investigations have been carried out for only comparatively few languages, such as the Australian language Warlpiri (Hale, 1983; Jelinek, 1984; Simpson, 1991; see also Austin and Bresnan, 1996), the Iroquoian language Mohawk (Baker, 1996), Salishan languages (Jelinek and Demers, 1994; Jelinek, 1995), the Athabaskan language Navajo (Jelinek, 2000), and Inuktitut (Eskimo) (Nowak, 1996a,b). Discussions of Algonquian languages seem to point in the same direction, but do not yet cover a broad range of relevant tests. Other languages suggest themselves as promising candidates, but have not been scrutinized, as is the case with most of the languages discussed by Mithun (1984, 2001).

The morphological representation of the core grammatical relations is frequently accompanied by fundamental shifts concerning the nature of lexical categories. Many argument incorporating languages feature a wealth of lexically and/or functionally bound morphemes (affixes) that have no independent lexical counterparts, and the proportion of roots and stems as compared to bound morphemes is dramatically changed in favor of the affixes (Nowak, 2005, 2004, pp. 35–61).

In Inuktitut (Eskimo), whole semantic fields denoting activities, states, events, processes, including the most elementary predications 'being' and 'having,' as well as the indication of reported speech and epistemic specifications are expressed exclusively by bound morphemes that are suffixed to the stem they modify or supplement (Nowak, 2004).

'he pretends to leave'
(Starks, 1992, p. 127)

In the Salishan languages of the American Northwest Coast, bound morphemes cover the domain of referential expressions and do so exclusively; so-called 'field suffixes' such as -éné, -né, 'ear' in ex. (7) lack independent counterparts.

(7) Kalispel (Salishan)
na•céné 'he gets an earring'
(Vogt, 1940, p. 53)

(8) Shuswap (Salishan)
s –cy –cyép –ø
STAT-PLUR/REDUP-stand.upright-3.itr
'the trees'
(Kuipers, 1974, p. 100)

Complex predicates are lexicalized as referential expressions, as in ex. (8). The same has been reported of Iroquoian languages (Lounsbury, 1953; Sasse, 1988).

In cases where items with lexical content are incorporated, no matter whether they are free or bound morphemes, typically the incorporating argument and the incorporated lexical items do not exhibit agreement. Yet some cases of such internal agreement relations have been reported. For Southern Tiwa, obligatory incorporation is reported. In this language, person marking on the complex verb also reflects the person, number, and class of the incorporated noun (Allen et al., 1984, pp. 295–298). The same seems to be the case with Bininj Gun-wok, a language of North Australia.

(9) (a) Bininj Gun-wok
ba-ginje-ng gun-ganj
3/31-cook-PP IV-meat
'(S)he cooked (the) meat'
(b) Bininj Gun-wok
ba-ganj-ginje-ng
3/31-meat-Cook-PP
'(S)he cooked (the) meat'
(Evans, 1999, p. 259)

Grammatical Incorporation

The most complex incorporating processes cover major grammatical operations. Syntactic operators such as auxiliaries, lexical pronouns, adpositions, complementizers, and other syntactic function words do most often not exist at the word level at all. Consequently, syntax is greatly reduced. Most important, syntax does not provide expressional alternatives for the speaker.

(10) Warlpiri
pingka-rlipa mata-ma-ninja-kujaku ya-ni
slow -1pis tired-CAUS_INF_PURP_NEG go-NPST
'We'll go slowly so that it (walking a long distance) doesn't tire us out.'
(Simpson, 1991, p. 108)

Lexicalization processes and lexical productivity equally take place on the morphological level. Affixes do not constitute closed classes.

(11) (a) Inuktitut
niuvirvingmuaqtunga
niuvirvik –muaq- -tunga
shop -go.to- -1s.itr
'I am on the way to the shop'

The term *niuvirvik* 'shop' is a lexicalized affix combination, as is *-muaq-* 'go to'. *niuvirvik* is composed of the verb stem *niuviq-* 'acquire' and a nominalizing affix *-vik* 'place where s.th. happens'; *-muaq-* is a highly frequent combination of the (singular) prepositional case *-mut* 'to' and the verbal affix *-aq-* 'go/move.' In Inuktitut, such lexicalizations are frequent and a source of lexical productivity. While some combinations became partly or totally opaque, many lexicalizations are structurally transparent and the affixes involved remain perfectly productive, as is the case with *–mut* and *–aq-*:

(11) (b) Inuktitut
illutinuaqtunga
[illu –tinnu(t)] –aq- -tunga
[house-term.1 pl.poss] –move- -1s.itr
[to our house]
I got to our place/I went home
(Nowak, 2004, p. 84).

Interestingly enough, the noun *illu*, 'house', marked by the prepositional case, fused with possessive marking, is not stripped of its plural *–nut* or the possessive when incorporated by *–aq-*, but the fully inflected adverbial expression is incorporated.

Beyond features such as person, number, and transitivity, incorporating arguments in many instances are fused with other features such as the indication of clause linkage, often referred to as switch reference, or anaphoric coreference, as can be seen in ex. (12).

(12) (a) Inuktitut
aniqumagu aullaqpuq
ani- -qu- -magu aullaq- -puq
go.out – order/ask/tell – 4s.3s.caus.tr leave – 3s.itr
because he (4s) told him(3s) to go out he left (3s)
'he told him to go out and so he left'
(Nowak, 2008, p. 29)

(b) Inuktitut
iqalliaqłuni anuraalikaallaktualuungmat …
iqalliaq- -łuni anuraa(q) –liq- -kallak- -tualuq- -mat
go.fishing -3s.part.itr wind -begin- -suddenly- - mighty- -4s.caus.itr
he going fishing because suddenly a mighty wind begins/began..
'he had gone fishing when suddenly a storm came up…'
(Nowak, 2002, p. 50)

Grammatical incorporation must be seen as the word internal establishment of grammatical relations without syntactic spell out. It results in highly complex forms equivalent not only to full propositions, the establishment of coherent discourse rests on it. Repercussions on information distribution and information structure are inevitable. In Inuktitut, e.g., incorporated lexical items are frequently picked up, referred to, and further elaborated in the course of discourse. Most important, they constitute preferred sites for the introduction new discourse participants/new information (Nowak, 2009).

Conclusion

It must be kept in mind that languages hardly ever represent ideal types. This applies to what has been said about syntax and morphology and the degree to which they interact. The types of incorporation discussed here exemplify an increasing complexity, configurationality, on the level of morphology, illustrating a unidirectional relationship between increasing morphological complexity and the morphological realization of arguments and grammatical structuring. Languages of high morphological complexity also feature the morphological realization of arguments, but it is not necessary that all languages realizing their arguments morphologically must be morphologically complex in other respects.

The specific morphological strategies employed range from concatenative (Eskimo) through template (Athabaskan) to morphophonemic and prosodic devices (Salishan) and often exhibit mixtures of all these types. A unified account of such complex and multilayered morphological patterns is a desideratum that must be left for future research.

While noun incorporation is a matter of choice in discourse, argument incorporation and grammatical incorporation are of a fundamentally different nature. They represent the sole way of expression and cover the full range of structural capacities. The last type, grammatical incorporation, extends morphological configurations to other than argument relations, i.e., to grammatical relations in general. This is the content of the traditional term 'polysynthetic.'

Abstract

Linguistics, the scientific study of language, has generated a wide range of branches, subdisciplines, schools of thought, and applications. This article provides a perspective within which these aspects can be interrelated, insofar as they use the word linguistics as part of their identity. It reviews the history of linguistics in the twentieth century, focusing on its claims to scientific status, and providing a classification of the subject in terms of its synchronic/diachronic, theoretical, descriptive, and comparative orientation. A second level of classification is based on the kinds of interaction which have emerged between linguistics and other disciplines, notably in the domains of culture, biology, and numerical sciences. The various branches of applied linguistics are reviewed, and several terminological extensions of the subject identified.

Linguistics, conventionally defined as the scientific study of language, has generated a wide range of branches, subdisciplines, schools of thought, and applications, many of which are given separate treatment in the encyclopedia. This article provides a perspective within which these and other aspects can be interrelated, insofar as they use the word 'linguistics' as part of their identity.

Linguistics as a Science

Linguistics achieved its academic identity during the twentieth century, shaped in the first few decades by a series of pioneering and influential personal statements (notably de Saussure, 1916; Sapir, 1921; Bloomfield, 1933), consolidated in the middle decades as a university subject at both undergraduate and graduate levels, and reinterpreted in the later decades by a new generation of scholars concerned to give the subject a sound theoretical foundation (notably Chomsky, 1957, 1965). In Europe, its origins lay chiefly in a reaction to the philological curiosity about the history and origins of language, which had preoccupied the nineteenth century; in the USA, the primary impetus came from a concern to provide a linguistic dimension to the anthropological investigations of American Indian cultures. But the subject also benefited from an increased general interest in the study of language in relation to human beliefs and behavior (e.g., in philosophy, theology, information theory, literary criticism, communication studies), which manifested itself at both popular and specialized levels. The development of the media, especially broadcasting, further helped to bring language issues to the forefront of national consciousnesses, as did the demands made by foreign-language teachers and other 'language professionals' for more sophisticated information about their subject.

The multiplicity of interests in the subject, each with its own intellectual agenda and methodologies of inquiry, brought a profound appreciation of the range and complexity of linguistic phenomena, and thus of the need to develop a research discipline with its own principles and procedures. Early on, linguistics came to be viewed as a 'science', and attempts were made to define its axioms and make its investigative procedures explicit (e.g., Bloomfield, 1926; Hjelmslev, 1943). Linguists emphasized their concern to make their studies systematic and objective, by contrast with the selective impressionism which had characterized much previous literary and pedagogical work on language. A great deal of attention was devoted to making investigative procedures clear and well defined. There was a significant growth, fostered by progress in acoustic technology, of experimental techniques, especially in phonetics. And there was an unprecedented concern for precise definition, clear and comprehensive description, and more powerful explanation. An emphasis in the first half of the century on the procedures for describing individual languages, or the features of language families, changed during the second half into an emphasis on the universal, defining properties of language, and on the nature of language viewed as part of human biology and psychology. Yet there were significant continuities too. Chomsky's focus on the distinction between linguistic competence and performance, and on the status of language as an 'organ of the mind', echoed Saussure's notions of the collective language system (*langue*) and its concrete manifestation in utterance (*parole*), and of the human language faculty (*faculté de langage*).

Because of its claims to scientific stature, the subject has often been referred to as 'linguistic science', but sometimes a designation of 'linguistic sciences' will be encountered. The choice hinges on the perceived standing of phonetics. In the 'plural' interpretation, phonetics is seen as a separate discipline, which along with linguistics makes up the linguistic sciences. The reasoning is that the subject-matter of phonetics – which includes acoustics, anatomy, physiology, neurology, and auditory perception – is so different from the 'rest' of linguistics that it cannot sensibly be subsumed under the same heading. Moreover, its methodology is very different, both in its experimental approach and in its reliance on technology. It is, some argue accordingly, a prelanguage study, and its findings need to be brought into relationship with those of linguistics. Others, however, point to the fact that the bulk of the subject deals only with those aspects of sound production and processing that are relevant to the production of spoken language.

Phonetics focuses on such entities as vowels, consonants, and pitch movements, and not on such noises as whistles, hiccups, and burps, even though these are also made by the vocal apparatus. Its aim is to explicate speech sound, and as it is speech which is the ground of being for all languages (writing being present only in a proportion of instances), this alternative argument sees phonetics as the 'indispensable foundation' (Henderson, 1971) for linguistics – one branch of a single linguistic science. (The term 'linguistics', of course, avoids the need to make a decision.) A similar issue appears when the focus is on speech alone. Speech science (or speech and hearing science) is the study of all the factors involved in the production, transmission, and reception of speech; but speech sciences will also be found, when there is a need to emphasize the constituent disciplines involved.

Classification by Orientation

These changes of emphasis and direction, which are an inevitable part of the intellectual development of a subject, have given rise to a range of designations for linguistics, each of which captures a particular orientation or 'universe of interest'. The earliest of these, introduced by Saussure, was chronological, distinguishing diachronic linguistics from synchronic linguistics. This terminology reflects his concern to move away from an exclusively historical approach for the study of language to one in which a language is seen as existing at a particular moment (or 'state') in time, 'syn-chronically', regardless of whatever may have happened to it previously or would happen to it subsequently. Most linguistic research is synchronic, in the sense that linguists are aiming to establish the nature of the system of rules which define a (part of a) language's expressive potential at any one time. For example, the word 'balcony' currently has a stress on its first syllable, and this is what would be noted as part of a synchronic description of modern English stress; the fact that, over a century ago, the stress was on the second syllable, would not be considered relevant. On the other hand, in a diachronic description, the way the stress has shifted is of central relevance – not least because the process is continuing in many other words, such as 'dispute' and 'research'. Saussure saw the two chronological orientations as intersecting – an 'axis of simultaneities' crossing an 'axis of successivities' – and this point of intersection must not be ignored. Uncertainties about usage are one example of the way in which ongoing language change complicates a synchronic analysis. But the point of the distinction is widely appreciated, and Saussure's refocusing has been so successful that it has long been standard practice to interpret the word 'linguistics' as meaning 'synchronic linguistics', with references to the other orientation requiring a more explicit phrase – usually, these days, 'historical linguistics'.

Another type of orientation relates to the generality of a linguistic inquiry. As already mentioned, a contemporary focus on language is to make statements of maximal generality: the aim is to determine what it is that defines the notion of 'human language'. All languages have a great deal in common in the way they produce sounds, organize their grammars, and construct systems of meaning in words. Identifying the universal principles which govern language, and demonstrating how these principles apply in individual circumstances to produce the languages known to us as French, English, Chinese, Swahili, etc., is the primary aim of theoretical linguistics. The term 'theory' here has its standard scientific application, reflecting the need for explanation of a maximally general kind, and the provision of fruitful models which will generate testable hypotheses about, in this case, linguistic structure and use. Theoretical linguists do not study a language because they are interested in that language per se; they study it because of what it can tell them about the nature of language in general. A particular language may be especially 'interesting' because it makes use of a type of sound or grammatical construction that other languages do not. The label 'general linguistics' is often used to capture this breadth of vision. A further consequence of this approach is that, once some linguistic data has been accumulated, a special concern is to find the best way of analyzing it. There are so many variables in pronunciation, grammar, and vocabulary that it is possible to envision an indefinitely large number of ways of showing how these domains are organized. Theoretical linguists spend much of their time searching for plausible and elegant analyses, and identifying criteria for their evaluation.

One of the controversies in the profession relates to this point. According to some linguists, as a result of the above orientation, the subject has become 'too general'. Analyses which try to achieve maximal generality inevitably make statements which are highly abstract, and seem to be far removed from the description of individual languages, and of the way these are used in everyday speech and writing. The emphasis on achieving generality, according to this view, has brought a de-emphasis on individuality – of what it is that makes one language unique, different from all the others. While it is accepted that, in the long term, all the idiosyncrasies of individual languages may be explicable with reference to general rules, there is seen to be no likelihood of this happening in the foreseeable future. In the meantime, the need to provide descriptions which are as full as possible is as important now as it ever was. Indeed, this focus on the special character of a particular language was given special urgency in the 1990s, when it was realized just how many of the world's languages are near the point of extinction. Of the 6000 or so languages in the world, it is widely thought that half are likely to die out within the next 100 years (Crystal, 2000). The need to make descriptions of the languages most at risk is therefore a priority for the subject, for once a language dies which has never been written down or recorded in any way, it is as if it had never been. This orientation for the subject, where the aim is to make as complete as possible a description of a language, in all its varieties, is usually referred to as descriptive linguistics.

It is not only the endangered languages which benefit from a descriptive approach, therefore. Descriptive accounts of English, German, Japanese, and all the other 'safe' languages are also important. 'Descriptive' here is being seen in contrast with 'traditional', referring to the tradition of language inquiry which antedated the emergence of twentieth – century linguistics, and which was characterized – especially in the field of grammar – by prescriptive and proscriptive rules about usage, purist condemnation of language change, and the distorted

description of modern languages through the use of a model of description derived from Latin. In the field of English, the need for more realistic description was the driving force behind many grammars, pronunciation guides, and dictionaries, especially from the 1950s on (e.g., Jones, 1956; Fries, 1952; Quirk et al., 1972). A particular consequence of this orientation was the provision, in some countries, of new syllabuses and materials for use in schools and teacher-training courses – a change of direction which in the later decades of the century brought not a little heart-searching, as teachers found themselves engaging in a close encounter with a linguistically based conceptual apparatus and a partly unfamiliar terminology. At a research level, since the 1980s the descriptive orientation of linguistics has been given additional impetus through the use of computational methods of data collection and analysis. Large bodies of data, in some cases consisting of several 100 million words, are now available as sources of evidence for descriptive statement, in a field that has come to be called corpus linguistics.

A considerable conceptual distance separates the description of an individual language from a general account of the properties of human language, so it is not surprising to find orientations which occupy aspects of the 'middle ground'. It is possible to extend the descriptive orientation 'upwards', bringing individual languages together in specific ways but without the inquiry necessarily bearing on a hypothesis about linguistic universals. This is the motivation behind comparative linguistics, where the purpose is to identify the chief similarities and differences between historical states of a language, between modern languages (e.g., those within a particular family, such as Romance or Germanic) or, in a more ambitious mode, between language families as wholes. This use of 'comparative' in fact antedates modern linguistics, being part of the designation of comparative philology, the subject which grew up at the end of the eighteenth century devoted to the historical comparison of Greek, Latin, Sanskrit, and their hypothetical antecedents, whence arose the concept of an Indo-European family of languages.

Applying the 'comparative method' to other languages which had written records was a natural extension, and philology (as it is today usually called) is practiced still, being distinguished from the orientation of historical linguistics partly by its aims and methods, and partly by the contrasting intellectual background (often from literature or history) of its practitioners. A related designation is typological linguistics, where the aim is to study the structural similarities between languages, regardless of their history, in order to locate them within a classification (or 'typology'). This is the only possible method in cases where there are no written historical records – a situation in which most of the world's languages find themselves.

When linguists talk about the structure of language, they are usually referring to the way a language can be analyzed into several dimensions susceptible of independent study. These dimensions are commonly referred to as 'levels' or 'components', though terminology varies widely between linguistic models. Most accounts recognize three major levels of linguistic organization: a sound system (or phonology, including its interface with phonetics), a grammatical system (with a division often made between sentence-structure (syntax) and word-structure (morphology)), and a semantic system (typically focusing on vocabulary (the lexicon), though not thereby excluding other ways in which a language's meaning is organized). The study of the written language necessitates the recognition of an additional level: an orthographic system (or graphology). And some linguists recognize other levels of analysis, such as one which extends linguistic inquiry above the sentence (a level of discourse, or text) or one which takes into account the way structure is altered when language is used interactively (pragmatics). Each of these terms has a variety of interpretations, depending on the theoretical approaches involved, but they all have one thing in common: they aim to explicate a domain of language structure, and are thus part of an orientation to the subject that might be legitimately called structural linguistics.

However, this designation has had a controversial position within the history of twentieth-century linguistic thought. In its early use, 'structural' linguistics referred to the particular approaches to phonology and grammar which were current in the 1940 and 1950s, in the work of such linguists as Bloomfield. There, the emphasis was on finding methods which would establish the contrasting units in a language's sound system (the phonemes), identify the elements of word formation (the morphemes), and analyze sentence constructions into their constituent parts. In a somewhat broader sense, developing the initiatives of Saussure, a 'structuralist' ethos prevailed, which aimed to establish systems of relations between linguistic units – an approach which, under the heading of structuralism, came to influence thinking throughout the arts and social sciences. Within linguistics, it was in due course applied to further areas of linguistic structure (especially semantics), and extended by some linguists (such as Pike, 1954–1960) to other domains of human communicative behavior. The notion of system continued to play a central role in linguistic theories which emerged during the postwar period, notably in the work of Firth (1957) and his students, and later became central in the systemic linguistics of Halliday (Halliday and Fawcett, 1987). It was the perceived limitations of the structuralist orientation, with its focus on the classification of structures and units at a 'surface' level of description within a corpus of data (linguistic 'performance'), which prompted its labeling as 'taxonomic' (with a pejorative implication) by Chomsky, and which motivated his initial formulation of generative linguistics (Chomsky, 1957), with its concern to explicate underlying linguistic relations in ways that could account for the creative linguistic abilities (or 'competence') of the individual.

Classification by Interaction

The generative orientation constituted a revolution in linguistic thought; and although other kinds of linguistic theories and models continued to be devised and developed in the latter part of the century, it was the generative approach, in its various formulations, which provided the subject's center of gravity. At the same time, partly independent of this state of affairs and partly as a consequence of it, several areas of interaction with other academic disciplines emerged. These 'hybrid' subjects were the result of a synergy between two intellectual streams.

On the one hand, linguists sensed that they needed to take their subject in fresh directions if they wished to account for everything that influenced the way people spoke and wrote (and also signed, for the analysis of deaf signing was also emerging as a new research field). On the other hand, scholars in other academic disciplines were finding that they needed to provide more sophisticated accounts of language structure and use in order to maintain their own research agendas. The potential for interaction had in some cases been recognized for many years. In the case of the interaction between linguistics and anthropology, it had been there from the earliest days of the subject (Boas, 1911). The difference was partly in the way hybrid labels came to be institutionalized as 'recognized' domains for teaching and research (anthropological linguistics, in this case), and partly in the cross-disciplinary climate of the times, which gave rise to nearly two dozen such hybrids by the turn of the century.

There is not always a total meeting of minds in these interdisciplinary encounters: the orientation given to the hybrid subject within a linguistics department is by no means identical with the orientation it is given within the department which constitutes the other half of the hybrid. For example, one of the areas of inquiry in psycholinguistics is the relationship between language and memory. When a linguist investigates how language is affected by memory and a psychologist investigates how memory is affected by language, it might be thought that the two directions of inquiry would 'meet in the middle'. In practice, differences in the researchers' intellectual histories, theoretical aims, and research procedures can produce widely divergent accounts. One need only look at the list of references at the end of journal articles to see how authors, ostensibly investigating the same subject, can come from different directions. There may be a difference of labeling, which may reflect a difference of orientation – as in sociolinguistics (a branch of linguistics) alongside the sociology of language (a branch of sociology), or philosophical linguistics (a branch of linguistics) alongside linguistic philosophy (a particular approach within philosophy). Nonetheless, the shared subject-matter, and a growing mutual familiarization with the intellectual background of the contributing disciplines, produced in the last quarter of the twentieth century a growing number of research collaborations, interdisciplinary conferences, jointly authored textbooks, and shared teaching courses in many of these hybrid subjects, resulting in a growing identity and coherence.

Hybrid subjects can be placed in clusters, on the basis of an overlap in their subject-matter. The earliest clusters to be given clear definition all relate to a concern to see language in its cultural and social context. Anthropological linguistics (or linguistic anthropology) focuses on language variation and use in relation to human cultural patterns and beliefs (in its early years, especially on the Amerindian peoples of North America). Overlapping with this is ethno – linguistics, studying language in relation to ethnic types and behavior, and widely practiced through approaches (variously called the ethnography of communication or ethnography of speaking) which analyze the entire range of variables, extralinguistic as well as linguistic, involved in social interaction. Sociolinguistics, studying all aspects of the relationship between language and society, is the most well established of this cluster of subjects, and is sometimes used as a covering label for all domains of inquiry in which there is a preoccupation with the social functions of language. However, sociological linguistics is sometimes differentiated from it, particularly in mainland Europe, reflecting a concern to see language as an integral part of sociological theory. So too is interactional sociolinguistics, referring to the study of speech in face-to-face communication.

Several other facets of the sociolinguistic cluster have maintained their individual nomenclature. One example is dialectology (sometimes called dialect geography), which focuses on the properties of regional (and more recently social) dialects. Another is areal linguistics, which studies the linguistic properties (languages as well as dialects) of large geographical regions – such as Western Europe or the British Isles. Closely related is geolinguistics (also geographical linguistics), which studies the geographical distribution of languages throughout the world with reference to their political, economic, and cultural status. Pragmalinguistics studies language use from the viewpoint of a language's structural resources; it contrasts with those pragmatic studies which examine the conditions on language use deriving from the social situation (sometimes referred to as sociopragmatics). Finally, there is the study of (linguistic) style, stylistics – a study which, though chiefly concerned with the nature of the personal linguistic identity of individuals (especially in a literary context), has often been extended to include the distinctive linguistic features of group-identifying functions of language, such as are found in advertising, science, and the media. When the focus is specifically on the distinctive language used in social institutions, such as law, medicine, and religion, some linguists use the label institutional linguistics.

Another cluster of hybrid subjects looks at language in relation to human biology. In its broadest characterization, the subject is referred to as biological linguistics (or biolinguisics), focusing on the preconditions for language development and use from the viewpoints of both the history of language in the human race and the development of language in the individual (the latter topic usually being distinguished by the name developmental linguistics or child language acquisition). Its topics include the genetic transmission of language, neurophysiological models of language production, and the anatomical comparison of humans and other species. It also subsumes the study of pathological forms of language behavior (as in aphasia, dyslexia, and language delay), though the complexity of these conditions, and the interdisciplinary nature of their diagnosis and treatment, has prompted the development of separate specialisms. Chief among these is neurolinguistics (sometimes referred to as neurological linguistics), which focuses on the neurological basis of language development and use, in particular aiming to understand the way the brain controls the processes of speaking, listening, reading, writing, and signing. Although its focus is on clinically normal states, much of its evidence comes from the investigation of abnormal language development and language breakdown. It thus overlaps with clinical linguistics, which is exclusively devoted to the diagnosis, assessment, and treatment of all forms of language disability in children and adults.

Any of these domains can of course be studied from the point of view of 'mind' as distinct from 'body', and

psycholinguistics (sometimes called psychological linguistics) has emerged as a major subject, investigating the interaction between language and such topics as memory, perception, attention, and personality, in normal and abnormal states. Depending on the domain of inquiry involved, compound names will be encountered, such as clinical psycholinguistics and developmental psycholinguistics. Psychology shares with education an interest in learning, and there has been special concern to understand how language is dealt with in schools and other educational institutions. Educational linguistics (sometimes pedagogical linguistics) focuses on the way government policies and planning, teacher training, curricula, syllabuses, and pedagogical materials handle the teaching of the mother tongue and foreign languages. The later decades of the twentieth century also saw a growing metalinguistic concern, with researchers investigating the ways in which children become increasingly aware of language and its elements, in a domain which by the 1990s had been labeled language awareness. Within the teaching profession, a corresponding fresh interest in the study of language, largely motivated in the UK by the arrival of the National Curriculum, introduced a new acronym, KAL (knowledge about language).

A further cluster of hybrids relates to the numerical sciences. Mathematical linguistics studies the formal properties of language, usually employing concepts of an algebraic or statistical kind. Its main application has been in the formalization of linguistic theory, as developed in relation to generative linguistics, but several other areas of language study have received mathematical investigation. In particular, statistical (or quantitative) linguistics studies the frequency and distribution of linguistic units in texts, with the aim of establishing general laws concerning the statistical properties of language (such as the relationship between word types and tokens), and identifying the distinctive characteristics of authors (stylostatistics). In the later part of the twentieth century, computational techniques and concepts came to be increasingly applied to the elucidation of linguistic problems, under the heading of computational linguistics. Several research areas have been developed, including natural language processing, automatic speech synthesis and recognition, machine translation, the making of concordances, and the many areas where statistical counts and analyses are required. The provision of large machine-readable texts (computer corpora) was a special development of the 1990s, and gave rise to the domain of corpus linguistics. Linguistic involvement in the other direction – in relation to such matters as computer programing, information retrieval, document identification, indexing, reference science, and knowledge management – has been limited to isolated projects, and has not yet resulted in a hybrid label, though one imagines that, given the growth in this area, the emergence of Internet linguistics can only be a matter of time.

Not all hybrid terms can be neatly clustered. Some, by their nature, stand outside of classification, because their role is to evaluate aspects of the field as a whole. The study of the history of ideas in linguistics is linguistic historiography. Philosophical linguistics studies the role of language in relation to the understanding and elucidation of philosophical concepts, as well as the philosophical status of linguistic theories, methods, and observations. Critical linguistics emerged in the 1990s with the aim of revealing hidden power relations and ideological processes at work in spoken or written texts. Critical linguists criticize mainstream linguistics for its formalist preoccupations, its lack of adequate social explanations, and its obscuring of ideological and political issues. This 'critical' perspective may be applied to individual branches of the subject. In particular, critical discourse analysis studies the relationship between discourse events and sociopolitical and cultural factors, especially the way discourse is ideologically influenced by, and can itself influence, power relations in society.

Applications and Extensions

The list of possible hybrid subjects involving linguistics is by no means exhausted by the above itemization, and new ones will doubtless emerge. A similar potential for expansion is also found in the various domains of applied linguistics. In its broadest definition, this is the application of linguistic theories, methods, and findings to the elucidation of language problems which have arisen in other areas of experience. The most established and well-developed branch is the teaching and learning of foreign languages, and sometimes the term is used as if this were the only domain involved. But several other domains of application have emerged since the middle of the twentieth century, including speech pathology and therapy, the teaching of the deaf, mother-tongue education, the writing of dictionaries (lexicography), the analysis of literary texts (literary stylistics), and translation studies. Quite restricted and specialized domains may be encountered. For example, theo-linguistics has as its focus the study of the way language is used in theological, biblical, and other branches of religious studies. Forensic linguistics is the use of linguistic techniques to investigate crimes in which language data forms part of the evidence, such as in the use of grammatical or lexical criteria to authenticate police statements. The field of forensic phonetics is often distinguished as a separate domain, dealing with such matters as speaker identification, voice line-ups, speaker profiling, tape enhancement, tape authentication, and the decoding of disputed utterances.

There is an uncertain boundary between applied linguistics and the various interdisciplinary subjects reviewed in Section Classification by Interaction, especially as several of those concerns involve practical outcomes (e.g., planning a national language policy within sociolinguistics). On the other hand, as these hybrid subjects develop their own theoretical foundations, the distinction between 'pure' and 'applied' is becoming more evident, and terminological distinctions such as that between (theoretical) psycholinguistics and applied psycholinguistics are now more regularly encountered.

The term 'linguistics' will also be encountered in a wide range of other contexts, where it is often no more than a loosely used synonym for 'school of thought' or 'approach', or even a stylistic replacement for the word language or grammar. Very general states of mind on the part of the investigator can be given a linguistics designation. For example, mentalist(ic) linguistics is contrasted with behaviorist linguistics. Macrolinguistics, representing a relatively broad frame of reference for linguistic inquiry, is opposed to

microlinguistics. In relation to schools, we find such usages as Cartesian linguistics (showing the influence of Descartes), Chomskyan linguistics (from N. Chomsky), Whorfian linguistics (from B.L. Whorf), Saussurean linguistics (from F. de Saussure), Firthian linguistics (from J.R. Firth), and neo-Firthian linguistics (scholars whose teaching derived from Firth's influence, notably M.A.K. Halliday (whose name has, in turn, been given to Hallidayan linguistics).

At this level, there is an appreciable overlap with the relevant aspect of language which is the focus of an approach – for example, the terms Chomskyan linguistics and Chomskyan grammar are often used synonymously, as are Whorfian linguistics and Whorfian semantics. The same point applies to such general approaches as functional(ist) linguistics, which treats the notion of function as central, especially in grammar, and thus allows a terminological overlap with functional(ist) grammar. Systemic and poly-systemic linguistics (which treat the notion of system as central) may also be found alongside systemic and polysystemic grammar. Virtually any variety or use of language can be focused in this way, as in creole linguistics (= the linguistic study of creole languages) and paralinguistics (= the linguistic study of *para*-language – tones of voice, facial expressions, etc.). But eventually, as increasingly restricted areas of inquiry are encountered, the use of the general term ceases to have a point, and linguists replace it by specific terms such as morphology, phonology, lexicology, semantics, onomastics, and other structural labels best explicated under the heading of 'language'.

Linked Lives

Abstract

This article refers to the Linked Lives, following the development of the life course theory during the 1980s and the 1990s and the seminal works of Elder and colleagues. In the first part the concepts linked to Linked Lives: timing, living in time and place, human agency are described in detail with examples from sociological, psychological, and developmental literature; whereas the second part reviews recent research that has employed advanced quantitative and qualitative methods using explicitly the theoretical principle of Linked Lives in the domains of family, migration, work and labor markets, and health.

The study of family and work life has been greatly enriched by the life course perspective, where the location of families in the broader social structure influences the events family members experience with the passage of time. Changes in mortality rates over the late nineteenth and all over the twentieth century (also referred to this as the Second Demographic Transition) coupled with changes in the macro- and microsocial environment not only expanded the human life span enormously, but also made lives intertwined in ways never imagined before. Life events such as marriage, giving birth, transition to work, becoming grandparent, or retirement have been transformed in normative social institutions that in their contemporary form diverge from the normative transitions in the pre-nineteenth century life, both with regards to their occurrence and timing (*see* Partnership Formation and Dissolution in Western Societies).

To understand the potential causes and consequences of change over time in the behaviors of individuals and families, and the ways the social structure plays a part in the changing nature of kin relationships, linked lives stemmed as a concept from the life course perspective and ecological paradigms that have emerged primarily from the intellectual traditions of sociology and psychology (*see* Life Course: Sociological Aspects). Previous analyses of families and individuals have mainly focused on discerning (1) the effects related to aging, (2) the effects of secular events, or historical period events, and (3) the interplay between aging and historical period events, also known as cohort effects. A debate between sociologists and psychologists in the 1980s over the dialectic of change and the importance of human agency and self-consciousness in the change process brought the focus on the need of a more holistic perspective in order to understand or explain family development (Marshall, 1986; Marshal and Rosenthal, 1991; Osmond, 1987). Developmental research that addressed individual life transitions as they relate to family changes, the interaction of individual and family changes with historical changes, and the relationship of earlier transitions to transitions occurring later in the life cycle (Harevan, 1987) cleared the way for developing the theme of families as agents and mediators of family change (Elder, 1977, 1981, 1991). Drawing upon symbolic interaction exchange and ecological theories, Elder and Caspi (1990) suggested that intra- and intergenerational processes can link the behaviors with specific family outcomes. Their study examined the complex interplay of historical and structural influences on individuals and families as they develop over time and paved a road to the understanding of linked lives.

Linked Lives in Life Course Perspective

As one of the main principle of the life course perspective, linked lives emphasizes the interconnectedness of lives, particularly but not exclusively linked by bonds of kinship. Proposed by Elder and Caspi (1990) as one of the five principles to examine the link between social change and the life course, it encompasses that "all lives are lived interdependently, and this connectedness defines a medium through which historical change plays out its influence over time" (Elder and Caspi, 1990: p. 221). In order to understand linked lives, the principles of lives in time and place (historical time and place), human agency, the timing of lives, and intergenerational transmission of behaviors are essential paradigmatic constituents of the life course perspective (Elder, 1994). Linked lives has provided a theoretical framework for researchers studying family, social stratification, labor markets, health and nutrition, and migration. More recently, researches have implemented the concept of linked lives to study physical activity, political activism, and social capital.

The principle of linked lives refers to the interdependence of lives – that the lives of individuals can be understood only as they are intimately bound to the lives of others. Social interdependence conveys that all individuals are embedded in a social structure where personal actions have consequences for others and the actions of others reflect on the self. The social regulation, structuring and support of human lives occur through interlocking relationships with significant others, tied by bonds of kinship and friendship. Across the life cycle of socialization and behavioral exchange in generational succession, opportunities and constrains become intergenerational, thus leading to interactive social worlds and networks of relationships over the life span (*see* Intergenerational Solidarity). Whereas social networks refer to the structural characteristics of social relationships (e.g., density, reciprocity) and support refers to the resources that flow from those relationships (e.g., emotional and financial assistance), the concept of linked lives considers that events that affect one person also affect other individuals in their networks.

Linked lives emphasizes the role of social institutions to define, segment, and construct individual lives in the interconnected domains of education, family, and work over the life course. Elder's study Children of the Great Depression (1974) traced the effects of drastic income loss to the life-experiences of the longitudinal subjects on their adolescent and adult years. This study that followed individuals and their families from the prosperous 1920s across the economic depression of the 1930s showed that not all families were devastated by the collapse of the economy. Namely, working-class and middle-class families had different experience due to individual-time and family-time differences and its conclusions were vital in the inception of linked lives. According to Elder et al. (2003), linked lives captures the interdependence of lives and the social and historical influences that are expressed through the network of shared relationships.

Linked Lives and Timing

In complementary ways with timing, linked lives addresses the temporality, process, and context of human lives and development. Both concepts also address the role of significant others in regulating life trajectories through networks of informal control (see Hagan, 1991). Life course trajectories are pathways, similar to that of a career (*see* Motivation: Life Course and Sociological Perspectives).

Timing refers to the way social roles and events are organized across the life course in a concept of age-grading, to a process of life management that schedules transitions in an appropriate way and to a location, both across the life course and history.

The trajectories of individuals are comprised of the sequences of roles and experiences that make up an individual's development. This critical developmental period specifies that events or exposures that occur at a particular or more vulnerable period of early life may have long-lasting effects on how an individual develops. The order of occurring of states is closely related to the meaning of age, and in essence to the stratification of the ways in which opportunities are made available to individuals in a population. Through family and intergenerational processes, adult development and life patterns are an integral part of child development (Parke et al., 1994: p. 35). Human capital and social capital are derived from the social relationships and working arrangements that sustain community life. The variations in human and social capital present a major turning point in the lives of children that will ultimately face different adult outcomes. A prime example of the interdependence of lives is the family world of farm children (Salamon, 1992). The link between farm households and community institutions such as the church, schools, and civic organizations contributes to the social capital essential for the maximization of the options of children and minimizing their risks (Furstenberg and Hughes, 1997).

Another meaning often applied to the timing of events in lives is the impact of experience and learning in adapting to external demands for change (Lazarus, 1999). These time role changes, such as becoming a parent during the child bearing years or becoming a widow in old age are considered normative transitions. However, turning points can involve changes in the direction of an individual's life and generally reflect nonnormative or unexpected events (*see* Life Course and Event History Analysis). Therefore, an account of the correspondence or goodness of fit of the individual with the environment is essentially connected to how normative or nonnormative the life course transitions in individual's life play out. The idea of person–environment link is closely related to the timing considered as normative transition of social institutions, or the right time in the ontogeny of individual's age for events like marriage, birth of a child, or retirement. Social institutions are predictable states or periods of the life course as the majority of the population is expected to experience such states, and their on- or off-timing is considered to be a significant predictor of the developmental trajectories of individuals. There can be a 'best fit' in the timing of individual development and family life stage, and their temporal convergence with structural and historically created opportunities (Elder et al., 2003). The changes in states or roles refer specifically to times in the developmental trajectory when the individuals make normative changes.

The interactive nature of relationships represents a life-long process, linking developmental trajectories, while the temporal arrangement of social roles provides a way of thinking about time as sequence. Children, spouses, partners, or parents, exert considerable influence on individual experiences and attainments over the life course. Of particular significance are the conjoint life course dynamics that span over generations and couples. Social roles expose individuals to the stresses and strains of others, as well as to the possibility of social support, therefore linking the concept of timing with linked lives.

Linked Lives and Historical Time and Place

Historical time and place captures the large events such as depression and war that can shape not only individual psychology, family interactions, and world views, but also create the opportunities and constraints that circumscribe the available choices and behaviors (Bengtson et al., 2005). Linked lives in time emphasizes the importance of social and historical context in shaping individual lives by affecting the timing and occurrence of role transitions over childhood and adult life.

Assigning people to cohorts according to their birth or other times of entry into society has been a starting point to distinguish between the explanations why some children grew up to be less affected by the negative events in their lives than others. Research comparing the life patterns of successive cohorts is prompted by the thesis that individuals can develop in different ways according to the nature of social change (*see* Age Stratification). Older and younger children will not experience an economic recession or depression in the same way because they differ significantly in their resources and social roles. Younger children, especially boys, were the most adversely influenced by the economic stresses of the Great Depression (Elder, 1979). Similar example is Hogan's (1981) study of conventional event sequences in the transition of adulthood among cohorts of American men. The conventional sequence of the end of education, work entry, and marriage has been

changed for a large number of young men who served in the Second World War, where more frequently, marriage came before the completion of education as veterans returned back to school. Cohort effects relate to linked lives not only through the developmental trajectories of children, but also through the timing and order of the life course transitions of adults. Historical events can produce different life course changes in successive birth cohorts. For example, a study of the four birth cohorts of women who settled in Elmira, New York (Bronfenbrenner, 1958) found employment before marriage to be the primary source why women delayed childbearing in the first two cohorts, who came of age during the Great Depression and during the Second World War, respectively. In the two younger cohorts, education played more important role in the lives of women, seen also by the trends of return to school following marriage and the birth of a child. Historical influence takes the form of a cohort effect when social change differentiates the life patterns of successive cohorts.

Another important aspect of historical time and place is the geographic setting linked to specific places and their properties. Qualitative studies that have brought evidence of the changing communities and their institutions give valuable insights to the understanding of families' and individuals' linked lives. Social interdependence linked by sharing the same geographic or physical space embeds individuals in a social structure where personal actions have consequences for others, therefore relating to linked lives. The social regulation, structuring and support through kinship and other relationships embodies the meaning of linked lives. Biographical and historical timing had consequences for the demographic behavior, occupational outcomes, and psychological well-being. Regardless of the importance of historical events, which can be operationalized as cohort effects or period effects (that occur when a historical event has a similar effect on multiple birth cohorts), living in place proves to be a challenging concept in times of great special mobility.

Linked Lives and Human Agency

Human agency is based on the assumption that humans are not passive recipients of a predetermined life course but make decisions that determine their lives. Within the constraints of the individuals' own worlds, people are competent to make choices among alternatives that form and can change their life course. Choices have transitional consequences and they may entail a turning point, thus, some decisions require intense focus on the present and others are influenced by long-term goals, giving agency a distinct temporal orientation (Hitlin and Elder, 2007). Linked lives refers to the embeddedness of the life course, where individuals are actors who behave or decide in a social context in which they may not adhere to a previously written script, written for them by the particular social categories that they occupy (Granovetter, 1985: p. 487). In addition, human agency necessarily transcends individuals as the consequences from individual actions necessarily are ascertained by their broader social networks.

The continuity of behaviors across the life course is sustained in social interaction (by its cumulative consequences) and there is a tendency these styles to evoke maintaining reciprocal responses from the environment (Caspi et al., 1989). This refers directly to linked lives as the agency in the selection of particular roles or situations represents a mechanism through which life advantages and disadvantages may begin to cumulate. In that way, behavior is sustained or changed by its consequences. An example for that is how competence in adolescence is rewarded by others, which in turn predicts adult competence in the late middle years (Clausen, 1993). Both individual dispositions and family values may favor a choice of compatible environments, which in turn should reinforce and sustain the match. For example, antisocial youth tends to affiliate with similarly problematic youth, and this interaction accentuates the antisocial behavior, which over time produces cumulative disadvantages. The cycle of cumulative disadvantage can be broken by new life transitions into different environments that will assist the process of change by establishing potential turning points for a troubled life course (Laub and Sampson, 1993). For example, marriage and employment can help young men who previously exhibited antisocial behaviors to transition toward more conventional lives by providing a network of individuals to reinforce conventional behavior. Conversely, negative life events such as spouse bereavement or even divorce can put individuals on a track of cumulative disadvantage, also affecting the lives linked to those who experience the events firsthand.

Linked Lives in Changing Context: Overview of Quantitative Studies

Cross-sectional research brought positive evidence for the notion of 'linked lives' (Greenfield and Marks, 2006; Pillemer and Suitor, 1991), which investigated how circumstances in adult children's lives would have implications for the lives of their parents and, accordingly, adult children's problems would affect their parents' psychological and relational well-being. Using the 1995 National Survey of Midlife in the United States, Greenfield and Marks's study (2006) concluded that parents who reported having adult children with more types of problems demonstrated poorer well-being than parents who reported having adult children with fewer types of problems. Other cross-sectional research also showed that parents feel more ambivalent toward children when children have more problems in their relationships (Birditt et al., 2010). On the other hand, Milkie, Bierman, and Schieman's study (2008) using longitudinal data found no effect of children's divorce on changes in parents' level of depression.

The social embeddedness of the life course has also been researched with longitudinal data on parents and young children (Sigle-Rushton et al., 2005) and findings suggest that the relationship between parental divorce and subsequent childhood and adult disadvantage is not straightforward. Little evidence was found that parental divorce is linked with subsequent childhood and adult disadvantage. In research on partners in the same household, another study showed that spouses' resources do affect occupational attainment, especially in the case of the husband's resources on his wife's attainment than vice versa (Bernasco et al., 1998). In addition, the study also found negative effects of a wife's labor-market resources on

her husband's employment exit and positive effects on his occupational prestige score after a job change.

Studying the relationship between family members outside the household, Aquilino (1994) investigated how family disruption that occurred after children were grown had sizable effects on parent–adult child relations. He found that later life parental divorce lowered relationship quality and contact between adult children and parents, with particularly stronger effects for father–child than for mother–child relations, and stronger for father–daughter than for father–son relations. Kalmijn and De Graaf (2012) also studied the relationship between family members outside the household and their study showed that parents are affected by the demographic life course transitions of their children. Mothers experienced a decline in well-being when their children separated, and both fathers and mothers increased their well-being when their children married or begin living together. Fathers also experienced an increase in well-being when their children became parents.

Stretching over interdisciplinary borders, researchers have applied the concept of linked lives to the research of health. For example, living partners may provide a lifestyle environment for each other, sharing health habits and behavior. Being married is associated with more positive health habits in general and a review of the relationship between health and marriage found that married people practice more healthful behaviors (Schoenborn et al., 2004). The application of linked lives to the study of physical activity revealed that married adults were found to exercise less than unmarried adults, and having children under the age of five was negatively associated with exercising (Nomaguchi and Bianchi, 2004). With regards to health behaviors and physical activity, these relationships are important intervening units for affecting individuals – as part of couples, as members of families, and through networks of friends. For example, a physical activity and nutrition intervention for couples has been shown to be effective in improving health behaviors and potentially reducing the risks of lifestyle-related diseases (Burke et al., 2004).

In the context of family migration, Bailey et al. (2004) explored how family relations influence the migration decisions of partners in dual-earner households. They found that intergenerational links may increase the incidence of a return migration of later-life dual-earner households. In addition, scholars have posited a link between historical cultural losses and contemporary accounts of disruptive behaviors and mental health problems among indigenous people in the United States. Recent empirical evidence indicates associations between intrusive thoughts of historical losses (e.g., loss of land, loss of language) and affective outcomes including guilt, hopelessness, despair, anger, substance abuse, and depressive symptoms (Whitbeck et al., 2004). The concept of linked lives has also been applied to the research on racism, examining how experiences of discrimination encountered by one person may indirectly affect another. Discrimination may result in secondary effects such as financial strain, decreased relationship quality, and intimate partner violence (see review Gee et al., 2012). For example, past experiences with discrimination can shape a Black mother's involvement with her child's schooling (Rowley et al., 2010).

In order to fully understand stratification and labor-market research scholars started to acknowledge the degree to which employment histories and family processes are related. For that purpose, linked lives is used as an additional aspect that to large extent has been neglected in stratification and labor-market research, addressing the relationship between individual lives and social structure in a way that simultaneously seeks to uncover mechanisms of change. Blossfeld and Drobnic's work (2001, Drobnic and Blossfeld, 2004) incorporating a linked lives perspective found that interdependencies in couples exist with regards to women's labor market integration, with variations spanning across marriage cohorts and various countries. They also found evidence for the importance of class-specific differences in the division of labor between husbands and wives over the family life cycle in differing marriage cohorts and countries.

The various contexts of family, work, education, migration, and other fields of research that have employed linked lives are of great relevance and can gain the appropriate visibility through multilevel studies of not only families, but also neighborhood and community effects in the lives of others (Furstenberg and Hughes, 1997; Sampson et al., 1997). Taking into account country and cohort variations, longitudinal studies of individual change started to incorporate more a type of multilevel models, in which multiple time points are 'nested' within a person; or multiple persons are nested within families or within countries. A model with multiple levels has the ability to estimate an individual's growth within the larger social context. With advances in statistical models, there is an increasing ability to investigate lives by emphasizing the social dynamic of linked lives. Individuals' trajectories and transitions can be better understood using advanced techniques such as piecewise growth curve analyses, multilevel models, event history models, sequence analysis, and Geographic Information Systems analysis. These techniques suit the examination of changes that are associated with a particular event or critical period, but also have the ability to operationalize macrosocial indicators of influence, thus capturing the core of linked lives (*see* Life Course and Event History Analysis).

Qualitative Studies and Life Course Analysis

The potential for an analysis of interdependency through a focus on linked lives (Elder, 1974; Mason, 2004) resonates with the way well-being could be measured in developing countries. This has the potential to help counter the tendency toward methodological individualism that focuses solely on quantitative methods. In contrast to static measures of well-being, life course analysis facilitates a view that is particularly valuable given development studies' focus on how processes of change affect human experience over time. Life history research mainly employs semistructured interviews that aim to 'capture the concrete details of lives in context' (Cairns and Cairns, 2002: p. 292) without allowing data collection to be overwhelmed by standardized procedures in way that might destroy the 'intimacy' of narrative accounts (Davis and Baulch, 2011).

Therefore, the study of the connections that extend across generations and serve to integrate young and old makes use

of the life histories research. Qualitative life course analysis has great potential to examine both the perceived intentionality of individual's action (agency) and to evaluate individual's experience (subjective meaning) in the context of linked lives and changing times (Locke and Lloyd-Sherlock, 2011). Using narratives of linked lives, Locke and Lloyd-Sherlock (2011) explore the lives of 22 older people in Buenos Aires with respect to their lifetime relations with their children and their current well-being. In addition, they also conduct 60 in-depth semistructured interviews of young adults in Zambia focusing on their life trajectories from birth, through youth to early adulthood with an emphasis on education and employment. In both cases a strong emphasis on linked lives is present by exploring the role of family, friends, and other individuals, as well as on the influence of shifting social, political, and economic contexts on individual experiences.

Locke and Lloyd-Sherlock take an approach of tracking linked lives in a respondent-centric way, focusing on what respondents have to say about those who were important in their lives at various times, their relationships with them, and what it meant for them. By analyzing commonalities and differences in how informants referred to particular relationships, they expose the turning points or changes in circumstances of the respondents. These methods are more established in development studies where the value of qualitative research is well accepted. Developing the credibility of this methodology for a wider audience is still seen as a challenge as only a relatively small proportion of the data is available for academic scrutiny by others.

Concluding Remarks

The need for new concepts of human development that should apply to processes across the life span gave birth to the idea of linked lives. The influence of social and historical factors on networks of shared relationships is a crucial dynamic for the exploration of 'linked lives' (Elder, 2002). To understand how disadvantage can be linked both within and across the generations, it is necessary to consider contextual factors in individual accounts. Interpretations of these accounts must be situated within a robust analysis of 'the changing times' (Elder, 2002: p. 210), as well as the changing places they inhabit. This would not have been able without the pioneering longitudinal studies of child development (launched in the 1920s and 1930s) that have extended well beyond childhood. These studies followed their young study members up to the middle years and later life. In doing so, they generated issues that recognized that individual lives are influenced by an ever-changing historical context, noticing that the study of human lives calls for new ways of thinking about their pattern and dynamic.

In addition, next to studying the right time in the ontogeny of individual's age for events like paid work and marriage (Moen and Sweet, 2003), future avenues of research should devote greater attention to broader conceptualizations that would simultaneously incorporate school and parenthood (Macmillan and Copher, 2005). Delaying parenthood together with the increasing level of education, especially for women requires a hands-on investigation of the current trends of combining work and family. Further, contemporary societies are facing challenges such as population aging and aging workforce, therefore exploring linked lives in the context of prolonging working life and living healthy would be essential in understanding the intertwined ways in which individuals' lives meet societal change.

Abstract

The period from the early sixteenth century up to the end of the eighteenth century saw a genuine revolution in the cultural history of the states of Europe. This article charts the development of literacy, especially in Europe and North America, in the early modern period, arguing that this was the most important time in the history of literacy, marking the period of transition from restricted to mass literacy in the West. It also considers problems of methodology in measuring literacy and reviews some of the statistical data from various European countries.

The period from the early sixteenth century up to the end of the eighteenth century saw a veritable revolution in European cultural history. In the Middle Ages, it was taken for granted that only a select few knew how to read and write and that many of them made their living out of these skills as scribes and clerks. By the late eighteenth century, however, in the most developed regions of Europe, about 50% of men were able to acquire information from reading the newspapers, and the number of people who could write was steadily rising. The skills of reading and writing and, beyond that, the use of literacy, were rapidly gaining ground, to the detriment of oral communication. The body of written documents increased drastically; literacy made its presence felt more and more strongly throughout society. Printed books grew in number while becoming cheaper and more things were thought worthy of being committed to paper. Literacy extended its power to ever-newer sectors of a developing state administration and bureaucracy in early modern Europe. Surveys and certificates were drawn up and the use of written documents gradually squeezed out verbal evidence. Inevitably, people's mentality and ways of thinking underwent a simultaneous change.

Orally transmitted knowledge and the memory of the elderly lost a good deal of their former prestige, while respect for information set down in writing, which increasing numbers of people were able to decipher, strengthened. With the spread of calendars and printed maps, the concepts of space and time altered; numerically articulated, measurable time came to replace an image of a past drawn with vague, uncertain outlines. Acquiring writing skills alone did not necessarily involve a change in mentality. Owing to the gradual spread of literacy in society, however, more and more people were able to read the dates on printed works and this affected their way of thinking. People knew what the date was and how old they were, and tied events to specific days, months, and years. The traditional concept of time had rested on oral tradition and memory, associating the passage of time with events such as wars and plagues, and the changing seasons. This slowly gave way to the new concept based on literacy, supported by written documents. This article tracks the development of literacy, especially in Europe and North America in the early modern period, the most important time in history of literacy, marking the period of transition from restricted to mass literacy in the West.

Literacy: Definitions and Mutual Relations

Functional literacy, i.e., the capacity to read a newspaper, sign a check and write a short postcard at least, was an essential and indispensable precondition of the functioning of nineteenth- and twentieth-century society. These skills were, however, lacking in the majority of the population in early modern Europe.

Literacy is much more than just the capacity to read and write. It is the constant practical use of writing and of the written record. Literacy represents a different way of seeing the world and storing information from that used by illiterate people.

During the 1990s, very important research was carried out on literacy in ancient societies, evaluating in a new light data that had been available for centuries, but not regarded as sources of literacy: descriptions of reading and writing, orthography of mural epigraphs, and so on.

Literacy remains a very real problem in large parts of the world outside the West (and in parts of the Western world where there are poor schools, and where the phone and television have completely replaced letter writing and newspaper reading, etc.). However, literacy played a central part in European cultural and social history in the centuries between 1500 and 1800. Literacy is typically a phenomenon of transition – these centuries saw in Europe the transition from a restricted medieval literacy to modern mass literacy. After the invention of the printing press in the mid-fifteenth century, the quantity of written documents, from books to newspapers and leaflets, grew very quickly, and this encouraged more and more people to learn to read and, to a lesser extent, to write.

Illiteracy is by no means a synonym for lack of culture. The oral tradition and the oral culture of traditional societies are as important and precious as the written culture and literate world of modern societies. The oral tradition did not disappear with the onset of literacy: in early modern Europe there was a coexistence of the two cultures. The oral culture was not, however, an isolated island in the dominating literate world; illiterate people using orality lived very much in the middle of a society where the most important decisions were put into a written form, and where more and more people could read and write. There was a continuous interaction between the two worlds. Illiterates used written documents that they could not decipher, e.g., passes and documents concerning ownership of their

houses and land. Often the content of lost written documents was conserved only by orality, e.g., those concerning the migration of population or the origin of settlements. Such information was often kept in memory only by the tales of the old people in the villages who may once have read such lost documents.

General illiteracy influenced the exchange of information, making it difficult for the masses to maintain contact with the world outside their town or village. In the twenty-first century, it is natural for a literate man to write a letter and read a notice or a brochure. For the unlettered, though, this causes grave difficulties and requires the assistance of others. Until the widespread use of the telephone, large sections of society practiced writing mainly through corresponding with relatives. Even illiterates tried to exchange letters, which meant sharing their innermost thoughts with those who offered to commit them to paper.

Measuring Literacy: Problems of Methodology

The best sources for measuring literacy are census records. During a census every citizen was asked if he or she could read and write, or only read, or neither read nor write. However, such censuses were carried out only from the second half of the nineteenth century. As literate people generally came from the upper, richer strata of society, they had a higher general life expectancy than illiterates. For this reason we should not draw retrospective conclusions on literacy from the age groups of censuses, as it is not absolutely certain that literate and illiterate people died in the same proportion.

We can estimate the rates of literacy before the beginning of censuses by consulting descriptive sources and statistics of crosses and signatures. Descriptive sources such as travelogs, reports of state officials, data on elementary education, book production, and book ownership, cannot furnish reliable quantitative data on the literacy rates. However, these are valuable indirect sources because we can analyze the competence of the writing. It is only exceptionally recorded that someone had authenticated a document 'by alien hand, not knowing the letters'; in most cases, only a cross by way of signature or some characters suspiciously identical with those in other signatures show that somebody was illiterate. In sources such as witness depositions, however, hundreds of nobles, peasants, and burghers declared that they could not read, or this fact about them was recorded by travelers, state administrators, etc.

Good statistics on literacy rates in early modern Europe can be drawn up, however, only on the basis of enumeration of people who signed their names or who could only make a cross instead of a signature. For this purpose we need a representative cross-section of the society where the social rank and geographical position (and if possible, age) of the persons in question can be determined. Often, however, only males and only the better-off figure in the documents, or only one professional group is represented.

Statistical data hardly reflect the real state of affairs concerning literacy. The method of counting crosses and signatures rests tacitly on the supposition that all those whose signatures have been found could indeed write, while those who left merely a cross on documents were all lacking the skill of even writing their names. Both suppositions could be erroneous, because examples abound of counterfeit signatures being entered on behalf of illiterate people and of crosses made by people well trained in penmanship. This reflects the mentality of a given society: if literacy has already acquired prestige, even illiterates try to fake writing capacity; however, if the great majority in society are illiterate, handwriting has no authentication function and thus even village notaries make only a cross, even if they can write properly. This would not come to light unless we have more than one sample of the signatures or crosses left behind by the same person, which, in turn, presupposes a recurrence of the same name, whose bearer gave a signature at one time and a cross at another. The statistical data concerning crosses and signatures, therefore, reveal the attitudes of a community toward literacy, rather than the concrete spread of literacy: they speak about the community expectations concerning literacy, the pressures on semiliterate persons to sign the documents themselves, and on the genuinely unlettered to forge a signature. Such mentality only emerged, though, if literacy was on the rise in a society. In their totality, therefore, these statistics more or less do mirror the advance of literacy. There is no doubt that if we divide society strictly into literate and illiterate people, the major part remains concealed: the semi-illiterate layer of society that did learn something of the alphabet and later, in accordance with the community's wishes, either made crosses or wrote their name on official documents. The same applied to reading, too: those who were taught the letters at school but hardly ever read, could profit from the printed prayer books whose text they knew by heart (extensive reading). However, they did not fare well when they had to read a handwritten circular whose contents were unknown to them (intensive reading). The unlettered and the literate were in fact never separated as sharply as may be suggested by the rows of crosses and signatures. No clear-cut distinction can be made between fully illiterates, who could neither read nor write, and semiliterates, who could read but not write: both groups left crosses on documents. Yet there is no greater gap in levels of education than that separating those able at least to read, to gather information from written texts, from those to whom the world of letters is literally a closed book.

The greatest number of written sources and of sources on literacy are to be found where the levels of literacy were the highest, and obviously this greatly influences research on literacy overall. In England from the seventeenth century onwards, witnesses authenticated their testimony by putting their signature or mark on the records and people signed oaths of fidelity en masse. In several Western European countries, spouses and their witnesses also confirmed a marriage by signing or marking the marriage register. This explains why the marriage register is a major source for the spread of literacy. In France, marriage registers had to be signed from 1686, in England from 1754. The city of Amsterdam, one of the most literate places of the world in this time, required marriage registers to be signed from as early as 1578. In 1630, 43% of bridegrooms and 68% of brides made a cross; 100 years later in 1730, the proportion is 24 and 49% respectively. In 1780, only 15% of men and 36% women could not sign their names at their marriage.

The conquests of Napoleon Bonaparte open up new possibilities for the historians of literacy in Germany and Italy. These two countries, so important for the cultural history of early modern Europe, lacked similar mass sources in the sixteenth to eighteenth centuries for evaluation of literacy levels. After they became part of Napoleon's empire, however, the French system was introduced – thus, around 1800, we have a statistically relevant quantity of crosses and signatures from many regions of Germany and Italy, as they were parts of France at this time. In Central and Southern Europe, however, only the minister conducting the marriage ceremony was expected to write in the register, and it was not compulsory for eyewitnesses to sign their accounts in court. Witnesses confirmed their accounts only by taking an oral oath, without signing the document. This fact in itself is indicative of the lesser role literacy and writing played in these regions compared to Western Europe.

Reading, in contrast to writing, leaves no traces behind; that is why researchers into literacy almost invariably examine the ability to write – or more specifically, to produce a signature – and give up trying to gauge reading abilities as a hopeless venture. In several European countries, however, an extraordinary source lends scope for the examination of reading skills en masse: the Lutheran pastors in those areas made an annual survey of reading skills in their flock from the late seventeenth century. In the history of European literacy, a position of eminence is certainly due to Sweden (with Finland and Latvia, which still belonged to it at the time), Zurich and vicinity in Switzerland, and certain regions in northern Germany (seventeenth and eighteenth centuries) where the Lutheran faith thrived. In the course of Lutheran church visitations in these territories, records were made of, among other things, the reading skills of all adults, even indicating the grades – so an otherwise nonmanifest skill can be examined on the basis of a large sample. The Lutheran church believed it to be of great importance for believers to read the catechism and the Bible. Those reluctant to learn to read were denied communion at Easter. The Swedish model is especially interesting, as the church was pushing for better reading skills without enforcing writing capacities. As a result there was a huge gap between reading and writing abilities – in the eighteenth century almost everybody (around 90%) was able to read, but only few (around 10%) could write. Female literacy was rising, too, and the role of the mother as a teacher at home became very important, especially in the nineteenth century.

The Lutheran church records are, however, not the only sources for examining reading capacities before the age of censuses. In Hungary, when the county administration investigated claims to noble title, it asked the nobleman making the claim whether he had read, or only seen, the lost letters patent that would prove his nobility. In three different regions of eighteenth-century Hungary, 71, 74, and 55% respectively of the lower noblemen declared that 'as they cannot read at all' they had only seen, but not read, the lost document.

Literacy in Europe

England together with the Netherlands, was the most literate country in the world during the period. In the mid-seventeenth century, during the stormy years of the Civil War, Englishmen were required to sign oaths of allegiance several times; consequently, there are ample data available concerning the state of literacy in various parts of the county, in the form of thousands of signatures and signs. On examining these, David Cressy (1980) has found that in England in the 1640s, some 70% of men and 90% of women were illiterate. As regards the sixteenth-century situation, only estimates can be made. Cressy avers that in the middle of the sixteenth century, 80% of men and 95% of women could neither read nor write. The percentages around 1500 may have been 90 and 99 respectively, though this is a mere surmise as even in England no statistical data about literacy can be culled so early. The situation in eighteenth-century Britain is much better known. According to David Cressy's estimates based on the available sources, at the beginning of the century 55% of men and 75% of women could write their own names. In 1754, it was stipulated by law in Britain that the marriage register had to be signed by both the bridegroom and the bride. From that time onwards, therefore, the development of literacy can be traced on the basis of precise data. By the middle of the eighteenth century, the majority of men knew how to write, only 40% being unlettered, while the rate among women was 60%. In the second half of the eighteenth century, however, this dynamic progress came to a sudden halt. Until the early nineteenth century, illiteracy stopped falling in Britain. The social transformation that was taking place as a consequence of the Industrial Revolution was probably to blame for this – inner migrations and early child labor were not really conducive to literacy. In the second half of the nineteenth century, though, illiteracy in Britain all but disappeared. Between 1850 and 1911, the proportion of illiterate men decreased from 30 to 1%, and that of women from 45% to less than 2%.

France is the best researched of all countries in terms of literacy in the early modern age. From the age of Louis XIV, it was compulsory for brides, bridegrooms, and witnesses to put their signature in the register at weddings, thus leaving a wide scope for researches into literacy. In France in the eighteenth century, the number of literate people almost doubled, even though at the time of the outbreak of the French Revolution they were in the minority, the proportion of literate people in France grew from 21% in 1686–90 to 37% in 1786–90. Frenchwomen also lagged behind men – literacy among them grew from 14 to 27% within 100 years, while among the men it rose from 29 to 47%. However, averages that apply to entire countries hide what is really relevant – the huge regional differences that were so characteristic of this large country. That imaginary dividing line connecting Geneva and Saint Malo, which in the seventeenth century separated the literate northern and eastern parts of France from the more backward western and southern parts, was still clearly visible on the map of literacy at least a century later, and in the case of women's literacy, as late as 1866. This indicates that regional imbalances in the spread of literacy, as an important index of development, take a long time to change. When the French Revolution broke out, there were huge regional differences in the literacy of men. In Normandy and in the countries north and east of Paris, 90% bridegrooms signed the register in Brittany and on the Atlantic coast, their proportion was less than 10%. In the secluded regions of the Massif Central, the percentage of men who put

their signature in the register was 16, of the women a mere four while in Alsace-Lorraine the percentages were 83 and 44 respectively. The differences did not diminish until the second half of the century.

By the end of the nineteenth century, illiteracy had in effect been wiped out in France. While in 1854, 13% of bridegrooms were unable to sign the marriage register, the number decreased by 1900 to a mere 5%. Within the same period the proportion of illiterate brides decreased from 46 to 6%. Compulsory schooling put an end to the difference between male and female literacy, which had been a marked feature in earlier centuries.

The newly unified Germany presented a very mixed picture from the point of view of literacy, too. In the Prussian kingdom in 1871, 10% of men above 10 years could neither read nor write. However, this average was calculated again on the basis of very different regions: the proportion was only 2% in Hessen and 3% in Bradenburg, while in the Polish-inhabited region around Posen (Wrocław) one-third of the males (32%) could not even read.

For lack of relevant researches, there are no statistical data on literacy available from the Austrian provinces of the Habsburg Empire in the sixteenth to eighteenth centuries. After the modern census had been introduced, the available data testify to huge discrepancies between the provinces, dwarfing the differences between the various French or Prussian regions. In 1900, in the most developed provinces of the Habsburg Empire, in Upper and Lower Austria, and in Bohemia and Moravia, the rate of illiteracy in the population of 10 years of age and above was less than 4%. In the same time, in Galicia 56%, in Bukovina 66%, and in Dalmatia no less than 73% of the population above 10 was illiterate.

There are ample sources in Italy on the spread of education and culture and on schools in the early modern period; however, except for the provinces conquered by Napoleon, no statistics are available about literacy before the introduction of censuses in the second half of the nineteenth century. In the vicinity of Turin in 1710, excluding the town itself, 94% of brides and 81% of bridegrooms were illiterate; by 1790, the percentages had decreased to 70 and 35 respectively. In the Neapolitan kingdom in Campania province, in the mid-eighteenth century, 76% of those submitting tax returns could put only their cross on the document, even though only the well-off, and then only men, were expected to prepare such a return at all. The marked difference between the northern and the southern provinces is evident even from this single piece of information. Censuses reveal, on one hand, that in the whole of Italy in the late nineteenth century, illiteracy, which earlier had reached astonishingly high proportions, was rapidly diminishing; on the other hand, however, the gap between northern and southern Italy was huge. It had not disappeared by the early twentieth century – in 1901 in the northern region of Piedmont 18% of the population above six was illiterate, in Lombardy 20%, in Veneto 28%, while in Sicily the figure was 71%, in Sardinia 68%, and in Calabria 79%.

In Poland, we can observe huge regional differences, too. In the Voivodeship of Cracow at the end of the sixteenth century, the landed nobility was largely literate: 96.7% of the nobles who bore the title *generosus* and usually owned several villages, could sign their name, and the percentages remained unchanged over the next two centuries. Among women, however, literacy rose rapidly in the same period: while in the late sixteenth century, 51% were unlettered, by the seventeenth century only 22% remained so. Women continued to catch up with men in the eighteenth century, when a mere 15% put a cross on documents instead of signing their names. In the lower ranks of landed gentry or *nobilis*, who owned one or at most two villages, the proportion of illiterates made up 24% in the sixteenth century and 16% in the following century. In another study, the literacy of Polish noblemen was examined on the basis of tax returns submitted in and around Cracow. In 1564–64, 43% of the noblemen were illiterate. The vast Polish kingdom, however, comprised regions with very different levels of development. In the Voivodeship of Sandomierz in the seventeenth century we find circumstances very similar to those of the Voivodeship of Cracow: 99% of the noblemen bearing the title of *generosus* and 75% of the *nobilis* could write. On the other hand, the Voivodeship of Lublin lagged behind: while those titled *generosus* were almost entirely literate, only 65% of the women could write. Of the *nobilis*, compared to the 84% in and around Cracow, only 70% signed the documents, while barely 1 out of 10 women could write their names. Even this proved to be a highly developed state of affairs when compared to Eastern Galicia, where 8% of the magnates (*magnifici*), 11% of the *generosi* and 72% of *nobili* put a cross instead of their names as late as the early eighteenth century. In 1764, two-thirds of the participants of the diet called *sejm* held here could not authenticate documents by signing them.

In Vas county, Hungary, in the eighteenth century, only 2.5% of peasants could sign their names, and among the lower strata of the gentry only 26% could sign their names with 74% putting only a cross on documents. The first census to give an overall picture about the literacy of the population in the Hungarian kingdom was carried out in 1870. At this time three-fifths (58%) of the population of above 6 years of age in the historical Hungarian kingdom (part of the Habsburg Empire, consisting of Hungary, Transylvania, and Croatia) could neither read nor write. The figure for Hungary alone was 51%, 78% in Transylvania, and over four-fifths of the population (84%) in Croatia and Slavonia. There were huge differences between the various nationalities, however, in 1890, 63% of Germans and 53% of Hungarians could read and write, but only 9.7% of Ukrainians living in Hungary, 14% of Romanians, and 30% of Serbians. If Central Europe was lagging very much behind the developed Western parts of Europe, the difference between Central Europe and Russia, and the countries of the Balkan peninsula, was as huge.

No reliable data are available on the measure of illiteracy in Russia for the sixteenth to eighteenth centuries, but Jeffrey Brooks, historian of Russian literacy, gave his 1977 work on the period between 1861 and 1917 a telling title: *When Russia Learnt to Read*. At the 1897 census, only 21–29% of men and 13% of women could read. Literacy attained the highest proportions in the Polish provinces of the empire, even though this favorable position was relative indeed: 29% of men and 23% of women had a passive knowledge of the letters. In the European part of Russia, 28% of men and 10% of women could read, while the relevant percentages in Siberia were only 16 and 3 respectively. Development in the 50 years preceding World War I was rapid; however, while in 1880, four-fifths of new

conscripts did not know the letters, in 1913, only 32% of these young men, who were just above school age, were illiterate.

The line of the River Danube and the Carpathian Mountains, which separated Hungary from the Balkan Peninsula, was also a demarcation line between two worlds as regards literacy. Missionaries and travelers in seventeenth-century Moldavia and Wallachia noticed that hardly anybody knew how to read or write, and even some of the Greek Orthodox bishops could read only with difficulty. 'Of the nobles and the tradesmen, few know the Ruthenian or the Slav script,' and even the majority of priests were illiterate according to the Jesuits, although they may not have been impartial. The population of Serbia was largely unlettered as late as the early nineteenth century. Hardly any of the leaders of the Serbian uprising could read or write; the ruling Prince Milos was probably the only illiterate head of state in Europe at the time. According to contemporaries, when Serbia became independent, neither the priests nor the monks could read and write. There was little improvement in this situation in the following decades: even the 1866 census found that 96% of the population was illiterate; at the turn of the century, the number was 83%. The Balkan Peninsula remained very much a region of illiteracy even at the turn of the twentieth century: around 1900, of the population above six, 72% in Bulgaria, 60% in Greece, 78% in Romania, and 87% in Bosnia were illiterate.

For these parts of Europe, literacy remained very much a problem of the twentieth century – the Bolshevik Party launched huge literacy campaigns after coming to power in Russia. In North America, there were very high levels of literacy for New England – male literacy rose here from 70% in 1710 to 90% at the end of the eighteenth century. However, as these data were calculated on the basis of the wills of the wealthy, doubts must be raised about this very high proportion of literates. The 1840 census showed huge differences within the country: around 4% illiterate in the state of New York, compared with 20–28% in Georgia, North Carolina, Tennessee, and Arkansas. However, the African-American population showed high levels of illiteracy even after slavery had been abolished: in 1870, some 80% of adult blacks were illiterate and the figure was 44% in 1900. Massive immigration into the USA from Europe before the World War I, imported mass illiteracy: in 1909, 99% of Danish or Scottish workers in the United States were literate, but only 45% of Portuguese and 43% of Polish workers could read and write at this time.

In other parts of the world, literacy is a problem of today and tomorrow. Around 1960, the time of dissolution of the colonial empires, 81% of the population of Africa, and 55% of Asia's population were illiterate. According to various estimates, at this time roughly 40% of the world's inhabitants still could not read or write. There remains much to do in 1992 the illiteracy figures for Burkina Faso were 86%, in Bhutan 85%, and in Afghanistan 76%. Illiteracy remains a problem for mankind even in the third millennium.

Literacy and Orality

Wolfgang Raible, Freiburg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Orality and literacy are dialectical concepts, the meaning of one term depending on the assessment of the other one. Both have a medial and a conceptual side. While mediality is trivial, the conceptual aspect is best conceived of as a continuum, thus blurring any clear-cut distinction between orality and scripturality. The scale corresponds to a series of ever more complex and demanding textual genres.

In order to unfold its immense creative and changing potential, script has to meet the appropriate cultural – e.g., institutional – conditions. The respective processes of social transition and change tend to be slow.

One of them is the enrichment of alphabetic script by an increasing number of ideographic features and a layout taking profit of the two dimensions of the written page. In mathematics, this resulted in a revolution in the seventeenth century. Informatics, one of its more recent offshoots, leaves deep imprints in actual everyday life. Recently, it made possible the Internet that relies heavily on script, integrating other media as well.

Alphabetic script was and is also a most powerful metaphor in Western thinking, leaving deep imprints, e.g., in molecular biology.

The increase in literacy characteristic of our modern societies may prompt nostalgic attitudes hailing former states of presumably authentic orality.

Definitions

Concepts that are mutually dependent are called dialectical. This label applies to 'orality' and 'literacy': 'literacy' cannot be conceived of without 'orality,' 'orality' not without 'literacy.' Hence, their respective meanings depend on how the opposite notion is assessed: if orality is given a positive value, literacy appears as negative, and vice versa.

To give some examples: Marshall McLuhan (1962) started from an oral society which he thought was originally closed, attached importance to the spoken word, and had relatively fixed social roles. He opposed this idealized form of community to Western literate societies which, having transformed oral language into a visible code, were seen as depreciating the spoken word, practicing division of labor, compelling us to cope with different social roles. In this context, a particularly negative influence is attributed to the invention of printing. Whereas Jack Goody and Ian Watt (1962) saw the transition from orality to literacy more in the sense of a profit-and-loss account, Walter J. Ong (1982) took an opposite stance underlining the positive aspects of literacy, thus suggesting to us the positive kind of innovation McLuhan was only willing to attribute to the New Age of television which, in his view, takes already the place of literacy (Raible, 1994).

The rash and far too general judgments we can find in recent and even in current scholarly discussion suggest a more cautious attitude. The first question to be asked in the present context is: what do 'orality' and 'literacy' mean? Here we have to tell a 'medial' from a 'conceptual' or 'cognitive' aspect: the medial one is trivial – something we utter is either spoken or written – whereas the conceptual side is a continuum, intertwining orality and literacy. This 'conceptual' side needs some more consideration.

Communication by language is based on social convention. Hence, the utterances we engage in or exchange with others always reflect a socially accepted activity: somebody has to be 'welcomed'; we engage in 'small talk' with her or him, are asking 'questions,' giving 'answers,' making 'jokes,' engaging in 'gossip,' etc. Some more privileged persons 'pass judgment' on somebody, make an 'injunction,' pronounce a 'verdict,' or proclaim an 'encyclical.'

The highlighted terms in the preceding paragraph describe social activities accompanied – or even brought into being – by the use of language ('speech acts'). They represent a continuum of text types that can best be arranged on a scale. Its one end can be termed 'interactive text,' the other one 'edited text' (Biber, 1988); other labels are 'conceptually oral' and 'conceptually written,' i.e., highly planned and edited text (Koch and Oesterreicher, 1994). For a similar distinction, Karl Bühler (1934) had already introduced a pair of Greek terms used by Wilhelm von Humboldt in the nineteenth century: language as 'enérgeia' (activity) versus language as 'érgon' (the result of activity: a work), i.e., language as an activity or process (involving present partners), as opposed to language as something created, produced, edited, for instance in the form of a book. What is increasing from one end of this scale to the opposite one is, among other things, the degree of planned structuring and, at the same time, the degree of intersubjectivity. Conceptually scriptural utterances should be accessible to a larger and less specified public, not just to the person I am speaking to.

The implications of the conceptual scale can best be shown within a three-level approach to 'language' (**Table 1**):

Each one of levels (a) to (c) should be conceived of as a scale, reflecting exactly the conceptual and cognitive scale holding between orality and literacy: on level (b), we are confronted with 'text types' showing an ever increasing degree of editing and planning. Stylistics and rhetoric belong to this level, rhetoric being, indeed, the art of planning effective texts in successive steps. We start with a general idea and a global strategy; then follow linear organization and memorizing; even the delivery is planned.

Table 1 The conceptual continuum and its exemplification on three levels of 'language'

	Cognitive scale		
	Wilhelm von Humboldt		
	Enérgeia	← →	*Érgon*
	Peter Koch and Wulf Oesterreicher		
	Conceptually oral	← →	*Conceptually written*
	Douglas Biber		
	Interactive text	← →	*Edited text*
(a) 'Language' as utterance	e.g., chat with a neighbor	← →	e.g., papal encyclical
(b) 'Language' as speech act types	e.g., small talk, gossip, joke	← →	e.g., novel, textbook, judgment
(c) 'Language' as the system	enables dialogue, etc.	← →	enables judgment

On level (a), we find the respective realizations, i.e., 'utterances' occupying – like small talk – one end of the scale, or, in case of a judgment or a patent specification, the other one. (c) is the level of the corresponding 'systemic prerequisites': composing texts belonging to elaborate text types demands a much higher mastery of language than buying bread or joking with our neighbor – witness legal texts: a French judgment comes as one single sentence with up to ten degrees of syntactic embedding (Krefeld, 1985). As we may observe in diachrony, language systems develop according to the communicative requirements they have to meet (Raible, 2001b).

Hence, conceptually speaking, orality and literacy are thoroughly intertwined. The often-postulated 'great divide' between orality and literacy, between 'oral' and 'literate' societies, simply does not and cannot exist (Hornberger, 1994).

Transitional Aspects

The mutual relationship between orality and literacy holds all the more as the existence of a script does not change or achieve anything by itself. Beyond doubt there is an immense creative and changing potential in literacy. But in order to unfold it, literacy has to meet the appropriate cultural and institutional conditions, above all the existence of an adequate education system (Scribner and Cole, 1999).

There are, nevertheless, some evolutionary tendencies. One of them is that literate societies are likely to develop, starting from the "communicative genres of everyday life" (Knoblauch and Luckmann, 2004 in the aftermath of Alfred Schütz), a far greater number of textual genres, along with new – e.g., legal – institutions. This enlarges the conceptual space shifting considerably the societal achievements of conceptual scripturality (and augmenting the time it takes us to acquire them). There will be neither essays, nor editorials, patent specifications, or testaments in an oral society (e.g., Biber and Vásquez, 2007; Bazerman, 2012; Bakhtin 1953/1986 is fundamental.).

The proliferation of textual genres accompanied by the extension of the conceptual scale automatically requires new possibilities on the systemic side. This is shown, among other things, e.g., by the fact that a considerable number of English speech act verbs appear for the first time in Early New English: 'to acknowledge,' 'to advocate,' 'to assert,' 'to concede,' 'to remind,' 'to apologize,' 'to question,' 'to request'; or even only in New English: 'to remark,' 'to retort,' 'to state,' 'to accept,' 'to guarantee,' 'to volunteer' (Traugott, 1987). Together with the speech act types already mentioned, these examples enhance at the same time institutional aspects of literacy.

One further general tendency is the slowness of all processes bringing about cultural change. To say it with a concept of Fernand Braudel (1902–85), they tend to be phenomena of the 'longue durée' (long-term). Some examples shall illustrate this.

Alphabetic Writing, Orthography, and the Invention of Printing

There are two kinds of writing systems: those representing formal aspects of speech ('syllabic,' 'alphabetic script'), and those rendering content ('ideographic script'). Writing proper names is a task that regularly leads to syllabic or even alphabetic elements in ideographic script (witness Egyptian or Maya hieroglyphs), whereas alphabetic script tends to become ever more ideographic. Alphabetic script with its reduction of written language to a series of 20–30 graphemes is an elegant invention. But whereas words or syllables are units immediately audible, the phonemes corresponding to graphemes are not. This leads in numerous cases to a developmental reading disorder, or dyslexia, a condition unknown in this form in ideographic or syllabic script.

By reflecting essential aspects of spoken language, early Greek script is characteristic of early alphabetic writing in general: since we do not hear pauses between words, 'scriptio continua' (continuous script) is, with some exceptions, a quite natural outcome. It prevails in Western texts up to the eighth century AD and is necessarily linked with reading out aloud.

By 1200, all the achievements of what most of us would call modern layout are present in scholastic texts: spaces between words, punctuation, capitals at the beginning of a new sentence, paragraph indention, emphasis by means of different colors and different script (all of them ideographic features), chapter headings, short summaries in the margin, footnotes, a table of contents, and alphabetic registers. As a result, the reader is not lost in an amorphous text. It is only at this time that the general practice of silent reading can begin (Parkes, 1976, 1992).

Such developments are due to a feedback loop: the higher the number of readers, the more will their needs be taken into account by the invention of features facilitating the reading process – as are ideographic elements. This explains why such phenomena can be observed at the end of the twelfth century: it was not until then that lay literacy developed to any significant extent.

By this time, we observe an incredible increase in the production of written documents. In the State Archives of Siena, there are for instance about 500 documents from the twelfth century, but nearly 17 000 for the thirteenth century. This acceleration of text production coincides with major changes in social, commercial, and agricultural organization. Thanks to doings and dealings, the city states of Northern Italy – a similar evolution can be observed in large parts of central Europe (for

England: Clanchy, 1993) – had already a population surplus. This compelled them to organize life and everyday supply very strictly by written statutes.

As a consequence, there was an immense need for knowledge: how shall I write a letter, make a speech, a treaty, how do I behave well, in short: 'how to win friends and influence people?' This was the time when, at Bologna, Roman Law was rediscovered; when the great Encyclopedias of the Middle Ages were written, when Italian merchants came to invent paper money as well as the new juridical forms of joint stock companies and insurances. In Art and Science, this was the epoch of Gothic architecture and Scholasticism (1100–1450), mediated by the contact with Arabic culture and the discovery of Aristotle. In this 'longue durée' perspective, the invention of printing presents itself much more as a necessary consequence than as an "agent of change" (Eisenstein, 1979) in the domain of literacy.

There was, nevertheless, at least one topic fostered by printing: discussion on orthography. On the one hand, printing books for a great variety of unspecified readers inspires thoughts on standardization. On the other, it goes without saying that all the achievements made in writing and layout increase the intellectual and the practical effort of the writer. This is why discussions on orthography tend to be dominated, since the sixteenth century, by elementary school teachers who would like to reduce – for those learning to write – the difficulties brought about by the ideographic tendency under discussion (Strobel-Köhl, 1994).

Material Aspects of the Written Text

The evolution of layout has an aspect that merits some more attention. Unlike one-dimensional spoken language, written text comes in two dimensions. Layout implements the potential of this two-dimensionality by making visible chapters, paragraphs, and so on.

The possibilities given with two-dimensionality are not limited to layout, though: Its potential enabled, among other things, modern mathematics. Thirteenth-century mathematicians were far from being familiar with the system of notation their successors use today. This system only took shape, between the thirteenth and the seventeenth century, in one of the transformation processes whose slowness was already mentioned. Most of today's symbols are the outcome of an intermediate stage presupposing alphabetic literacy: the stage of abbreviation. It leads not only to most familiar signs like '&' ('et'), but also to the plus and minus ('+', '−'), the symbol for the square root, etc. Eventually, it was Descartes who, at the beginning of the seventeenth century, introduced the modern conventions holding for the symbolization of the unknown element. All of this facilitated the highly momentous discoveries made during the seventeenth century: analytic geometry and calculus, resulting in a new ideographic system (Raible, 1991).

Mathematical ideograms, consequently exploiting the two dimensions of the page, are accessible to simultaneous rather than to linear perception – provided one knows the system. This enormous progress made mathematics the most important complementary discipline to natural sciences, contributing in a decisive way to their role in our modern world (Krämer, 1991). This is why, at the beginning of the seventeenth century, Galileo Galilei tells us that the *Book of Nature* is written in cipher and that those intending to read it have to master the language of mathematics.

In recent times, this role has partly passed to a new branch of mathematics, informatics. Texts written in programming languages are at least as demanding as complex written texts in natural languages (Raible, 1999). At the same time, their influence on modern life is pervasive. Retrospectively, the second part of the twentieth century is likely to appear as the age of Claude E. Shannon (1916–2001), among others the father of information theory.

The Written Text as a Metaphor

The use of written language as a metaphor has a long history, too – think of the *Book of Nature* (Blumenberg, 2007[1986]). The metaphorical use starts with the early atomists, Leucippus and Democritus (fifth century BC). Their basic idea was that the complex, variegated, and manifold world surrounding us is nothing but appearance, whereas in reality all was thought to consist of atoms and the void between them. According to what Aristotle tells us in his *Metaphysics* (985b15ff.), their visible model for the invisible structure of matter was alphabetic script. The diversity of the visible world would be due to the fact that the atoms are differently shaped – just as an A differs in shape from an N; that their order may be different – as the sequence AN is different from NA; finally, that their relative position in space may differ: a rotation of 90° makes an N out of a Z.

The central idea underlying this conception is to reduce multifold diversity onto a restricted set of elements (here the 20-odd letters of the Greek alphabet) making up for a possibly infinite number of written texts.

While the *Book of Nature* became a powerful and influential metaphor since the Middle Ages, the idea of the alphabet as the basis of a code reappears at the end of the nineteenth century in cell biology (Friedrich Miescher, 1844–95). It was again put forward in 1943, this time by the Austrian physicist Erwin Schrödinger (1887–1961), in a series of lectures given under the heading "What is life?" where he suggested a genetic alphabet similar to the Morse code. His suggestion was confirmed in 1953 by Francis Crick and James Watson, who showed that the long strands of DNA (Schrödinger's punched Morse tapes) are structured as a double helix, and by the series of momentous discoveries following this breakthrough.

Since then, the metaphor of written language in its alphabetic form is pervasive in molecular biology. The four nucleotide bases abbreviated by A, T, G, and C were called 'letters of the genetic alphabet.' RNApolymerase is 'reading' DNA sequences with their 'reading frames.' This process is called 'transcription,' and it happens thanks to 'transcription factors'; transcription is followed by an immediate process of 'proofreading.' The result is called a 'copy,' subject to further 'editing.' The resulting string of mRNA will be 'translated' into a polypeptide. This is made possible because the triplets of DNA 'encode' or are 'coding for' amino acids. The whole process is called 'gene expression.' It presupposes a 'grammar of biology.'

As the genome of humans and of other species is being 'deciphered,' the result is stored in large databases modeling the

sequences of nucleotides as sequences of the letters A, T, G, and C. In this context, molecular biologists are speaking of 'gene libraries.' Recurrent sequences of nucleotide 'letters' as well as recurrent sequences of amino acids in proteins are called 'motifs,' and the genome itself is seen as an 'encyclopedia' (Raible, 2001a).

Some Other Transition Processes

One of the disadvantages of 'oral' cultures is what was called a 'collective censorship.' Narratives the audience dislikes fall into oblivion. In literate societies all written texts can, in principle, be preserved and rediscovered by future generations. This advantage changes into a serious problem with mass media, including the Internet – this is not least a true consequence of printing.

Unless the public simply refrains from reading, there are at least three reactions. Long texts are transformed into shorter (and cheaper) versions. A lot of these text types were already created in Antiquity or in the Middle Ages, for instance 'epitome,' 'summarium,' 'argumentum,' 'catechismus,' 'breviarium,' and 'compendium.' Other genres create a new text out of parts of others (e.g., 'anthology'). Modern literary scholars cannot but use one of the vernacular versions of Valentino Bompiani's 'Dizionario delle Opere di tutti i Tempi e di tutte le Letterature' (Dictionary of the Works of all Times and Literatures).

A second reaction is an institutional censorship as embodied by all systems of education. They make use of specific 'curricula,' 'syllabi,' 'textbooks,' 'introductions,' and 'primers' in order to transform youth into fully fledged members of society. It will not come as a surprise that this kind of selection is subject to permanent discussion.

Making texts as attractive as possible, alongside with making their content easily accessible, is a third answer to the problem. The most radical changes in writing can be observed in the history of mass media, i.e., in journalistic writing and in the corresponding genres of television. Scientific writing is another good example: today, articles published in journals are structured according to an identical model and endowed with tables, schemes, pictures, whose captions and legends, together with the obligatory 'abstract' of the article itself, swiftly inform the readers (Bazerman, 1991; Gross et al., 2002).

The last point shows one of the problems, though: facilitating reception holds only for those who are already experts in the matter, with the cognitive demands of such texts increasing at the same time. Nevertheless even this strategy does not solve the basic problem. Thanks to specialization and to the accelerated growth of science, the number of scientific journals and articles published daily is so vast that we simply cannot cope with it. We should have read the relevant texts in order to know at least the State of the Art, though, before publishing, e.g., the findings of a new experiment. As a result, formerly well-established facts may fall into oblivion and are rediscovered a 100 years (or even more) later.

The presentation of information in the Internet repeats an evolution that took place in the layout of written text. Witness the plethora of new elements in subsequent releases of hypertext markup language (HTML or XML – they correspond to the third level in the above scheme) and the introduction of metatags leading, for web crawling machines, to the equivalent of subject catalogs in our libraries. The web pages of the Internet basically exploit the achievements of literacy (in traditional texts, footnotes, page references, a table of content, etc. correspond to 'links,' a major difference being only the quick availability of the objects referred to). New features are the availability of color, sound, and moving items.

At the same time, the Internet shows once again the potential inherent in a new medium, this time with a potentially unlimited communication radius. Thanks to the Net, the collaborative undertaking Wikipedia became, over a period of only 10 years, a most important source of encyclopedic information. Whoever has used an online dictionary will scarcely feel a need to revert to the printed version. Email, SMS, and Skype increasingly supersede phone calls. Chat rooms have more often than not become places where we can play with language thanks to ingenious abbreviation techniques (Strätz, 2010). Internet forums or the possibility to comment on newspaper articles show the double-edged nature of new forms of communication, though: on the one hand we can react almost immediately, on the other we tend to give way to unfiltered emotions and prejudices, do not care about thorough information, let alone orthography, our anonymity fostering even insults we would rather not make in front of a visible addressee.

A Precarious Equilibrium

There is no great divide, then, between 'oral' and 'literate societies,' orality and literacy being intertwined on the conceptual level. In addition to this, there is another factor of cultural variation: a social community can dispense with script, not with spoken language. Apart from entirely oral cultures, we are thus always confronted with more or less literate societies. Given the dialectical relationship between orality and literacy, this means a steadily changing state of equilibrium.

There are indicators showing us that the precariousness of this equilibrium is felt. As the evolution of culture in general may lead to the slogan 'back to nature,' the increase in literacy may make us long for the lost paradise of 'innocent' orality. This desire may materialize in a motto like "let us write the way we speak" (Bader, 1994). First examples were Plato's critique of literacy ('Phaidros' 275d) and the effectiveness of highly planned Sophist rhetoric giving rise to suspicion.

Anyhow, the consequence of such reactions is even more literacy. Since Antiquity, theoreticians of rhetoric know that among the genres of speech 'ex improviso speech' is the most artful one. Baldassar Castiglione (1478–1529) whose Courtier was a model for Europe since Italian Renaissance, tells us that true art means dissimulation of art. The same thing holds for the impression of orality called 'skaz' (derived from *skazat*, 'to tell') that was discovered and recommended by some of the Russian formalists and refers to oral characteristics showing up in written literary texts.

What at first sight might appear as paradoxical is quite obvious on closer inspection. Given the dialectical relationship, in a literate society orality has to be artificially created – just as seventeenth century authors conceive of nature – in literature and in the Fine Arts – as of 'the negation of the negation of nature.' Once a culture has adopted literacy, returning to 'authentic' orality is impossible.

Abstract

The concept of 'literacy,' while often contentious, has constantly evolved along with social change and technological advances. Even more so in the twenty-first century the unprecedented impact of digital technologies has produced new theories and research around the nature of literacy. We are able to communicate instantly with combinations of text, photos, or videos through mobile technologies and obtain instant information from the Internet. The phenomenon of Web 2.0 has raised levels of online interaction with social changes accompanying different patterns of communication. Due to these changes key questions are raised about literacy education in classrooms. Is reading and writing different in this digital, multimodal, and multimedia environment? How can we work across traditional views of reading and writing within this new communications environment? This article examines new views of literacy that are supported by worldwide research in schools and provides examples of practical articulation between new theories of communication and classroom practice.

Scenario

Susan, a pupil in a Grade 6 class in Sydney, Australia, uploads a digital narrative onto a wiki shared by students in a Year 6 class in Glasgow, Scotland. Susan's fictional narrative is about a family in crisis from the father's gambling addiction. The text has been created after work in her class on the structure of literary narratives along with research into social issues that affect children in families. It is a first-person narrative written from the perspective of the main character, a girl of the writer's age as she witnesses the impact of parental tension and loss of income on the family. The narrative is created on a touch pad with written and visual text, photos, music, and video clips. It is interspersed with factual information that is a result of Susan's research into gambling addiction. Each screen or page of her text displays web links, text boxes, photos, and graphics. The students in Glasgow read Susan's story and give her feedback, commenting on aspects they consider to work well and making suggestions for further improvement in her writing and digital design.

Introduction

This scenario is one small example of a literacy activity in a global classroom made possible with digital communications technology. The increases of digital, mobile media and touch pad devices have been predicted as precursors of technology that may be available in future classrooms, such as "touch screen tables, robot study buddies, and 3D virtual learning environments" (SMH, 2012). Today's students are able to communicate instantly with combinations of text, photos, or videos through smart phone technology, different types of computers, and multimedia devices and obtain instant information from the internet using these devices and their applications. With Web 2.0, social changes have accompanied these technological developments. Students can participate in twittering, wikis, blogs, and various social networking sites or engage in a virtual environment through gaming or joining virtual worlds. These communication environments are changing the way people present themselves and the way relationships are developed. Anticipations are that aspects of Web 3.0 are already occurring (Exa, 2011) in the way data information is integrated and accessed. These changes raise important questions. What do they mean for the notion of 'literacy' as we have understood it for several decades, and what are the implications for literacy education in schools?

Digital communication technologies have affected society so rapidly that educational researchers, policy makers, and teachers have only begun to consider the application of these changes for curriculum design and assessment. The multimedia facilities of digital technologies, particularly mobile hand held devices and touch pads, encourage the processing of several modes simultaneously. Thus reading and writing rarely occur in isolation within such digital communication, yet, traditionally, they are seen as separate processes. Teachers are challenged to adjust their pedagogy to this new environment and balance the incorporation of new modes of communication with those skills of reading and writing that are seen as core for a literate person.

There is often polarization of 'traditional' and 'new' views of literacy but in fact conceptualizations of literacy have always changed even though the term itself was not often used until the late nineteenth century (e.g., Barton, 1994; Christie, 2010) and then mostly in relation to mass elementary schooling. Even if we consider the commonly quoted view of being literate as the 'ability to read and write,' this is a reductive concept that does not allow for 'thinking' and 'meaning' (Green, 2012: p. 4) that has always been part of human communication. Recent terms such as 'new literacies' (Lankshear and Knobel, 2003), 'multimodality' (Kress and van Leeuwen, 2001), and 'visual literacy' (Arizpe and Styles, 2003) have been used in educational contexts, yet each of these refers to ways of interacting that have been part of basic human communication and meaning making for centuries.

There have always been 'new' literacies when new technologies have been invented, whether we consider the printing press, the fountain pen, biro, typewriter, or computer. Each of these physical, technical inventions contributed to sweeping social changes in the century in which each was invented and gave people wider access to communication and education.

Multimodal combinations of language, image, sound, movement, and gesture have always been part of communication between people as well as in more formal ways through theater, dance, and music. Visual literacy has always occurred where images have represented people, activities, and events such as in prehistoric cave paintings, in the complex art of the Egyptians, and in religious art and illustrated manuscripts such as the Bible and the Koran. It is not the purpose of this article to review the history of art, technology, or communication, yet it is interesting to remember that communication has always had a basis in language, art, movement, sound, and music. There have been different times when the combination of these has been more significant when enhanced by technological developments such as the phonograph, photography, film, radios and transistors, television, computers, and multimedia. Such developments along with associated social change have contributed to the organic, ecological nature of literacy.

There have always been new ways of communicating or 'new' literacies; however, as recently stated by Donald Leu (2012), we are currently in an 'epoch' of change that is more sophisticated and complex than ever before. This article provides a brief overview of 'new' aspects of literacy that have been enabled by technological and social changes. They are considered along with what is nominally called the 'traditional' view of literacy, which is based on written language in paper-based texts. In the previous edition of this Encyclopedia, Perfetti and Sendak (2001) presented a detailed and informative review of literacy education. They showed that concepts such as 'universal literacy' and 'functional literacy' vary within different cultures and countries and demonstrated the difference between 'narrow' and 'broader' views of reading (p. 8976). They provided a detailed overview of the relationship of reading to the writing systems of a language and the importance of decoding, particularly phonemic awareness for young children learning to read. These are foundational skills that are essential for literacy education; however, students now require a repertoire of both print and digital literacy practices for their future workplace and life. With the multiple media available for communication in the twenty-first century the potential for literacy education in schools is both challenging and exciting.

Literacy in a Digital Environment

If we consider the scenario at the beginning of this article, we can examine the language and literacy that was needed to achieve the outcome of Susan's work. Susan had to understand the features of a narrative, its purpose, and structure to write a fictional story using a first-person narrator. In addition, she needed different levels of comprehension as she researched, read, and selected relevant information on social problems caused by gambling. These facts were then woven into the themes of her narrative, along with appropriate use of grammar, vocabulary, and correct spelling. These are aspects of 'traditional' literacy that would be expected of a student in the final year of primary school. The traditional skills occurred along with the technical proficiency required for using and producing text on a touch pad, e.g., browsing and selecting websites by touching and tapping hyperlinks; navigating menus and icons; scrolling through text; moving photos from one screen to another; inserting video and music; composing on screen; and designing pages or screens with color, graphics, text, text boxes, and images. These are the combination of traditional with technical skills that have been referred to for some time as 'new' literacies (e.g., Luke, 1995; Street, 1997; Lankshear and Knobel, 2003).

The scenario about Susan demonstrates the integrative potential of digital communication so that it is difficult to separate the physical from cognitive processes, or reading from writing, within new communication practices. There are, however, significant aspects that need to be considered when contemplating the differences between traditional practices of reading and writing and those that are possible with digital communication. Thus reading and writing are discussed separately in the next sections to demonstrate key features that we need to consider for educational implications. Then their interrelationship will be examined within new communication contexts and implications considered for literacy education.

New Ways of Reading

Reading with screen-based texts entails the reading of text that is not usually in a linear format. On-screen reading incorporates multisensory activities such as searching, viewing, browsing, scrolling, hyperlinking, and navigating together with the clicking and scrolling of a mouse (or the touching, tapping activities with mobile, and touch technologies). Other modes that are interpolated along with written text are image, sound, movement, and gesture. Thus the term 'multimodal' has been used in recent years to describe the nonlinear construction of texts that occur primarily on a screen. The theory of multimodality (Kress and van Leeuwen, 2001; Kress, 2003, 2010) has been the basis for the contention that the simultaneous processing of different modes of text, image, sound, and gesture in visual, media, or digital texts is a different behavior from the linear, sequential processing of print-based texts. Several theorists and researchers have examined the nonlinear reading pathways of screen-based texts (e.g., Snyder, 1997; Kress, 2003; Leu, 2000; Unsworth, 2001; Walsh, 2006, 2010) while the 2009 Program for International Student Assessment (PISA) report (OECD, 2011) identifies differences between 'static' and 'dynamic' electronic texts (pp. 27–28) to identify different ways meaning can be processed.

The navigation of screen-based texts frequently involves various aspects of online processing that includes responding to animated icons, hypertext, sound effects, and navigating pathways between and within screens. A UK study (Bearne et al., 2007) provided evidence to show that students across an age range from 3 to 16 years use a range of skills and strategies for reading screen-based texts. Researchers' observations confirmed that students were involved in 'radial browsing.' They were able to trawl language, image, and music as well as highlight key sections to retrieve information. Students of today quickly adapt to the navigation potential and the processing of different modes within digital texts. This processing itself often incorporates a merging and synchronizing of text, images, sound, and movement as these occur in recent digital products, such as

touch phones or touch pads. The touch features of recent products rely much more on gestural, spatial, and kinaesthetic movements that need further investigation in the way this processing is affecting cognitive processes. New research (e.g., Walsh and Simpson, 2013; Rowsell et al., 2013) is examining the impact of touch on cognitive processes when reading and writing with touch pads.

There are important implications for literacy education when considering reading in a digital environment. Students need to be able to decode written language, understand vocabulary, and develop the same types of comprehension that have always been required for reading literary or factual texts. At the same time, they need to decode and understand the structure of different features of digital texts, particularly the nature and purpose of visual, gestural, or audio modes. They need to be able to navigate effectively between varieties of texts and understand the difference between scanning for information and sustained reading. Teachers need to model and scaffold students' reading experiences on and between screens, and recognize the need to build students' metacognitive processing and evaluation of digital texts. At the same time, critical and evaluative skills are needed to discriminate between sites and to detect authenticity and bias in the extensive material on the internet.

New Practices of Writing

Writing on screen has existed for a long time with word-processing facilities but now 'writing' very often entails designing and assembling a product that may contain written text as well as quite sophisticated layout, graphics, photographs, and images. Similarly, a 'writer' can become a 'producer' (Sheridan and Rowsell, 2011) by designing and producing a text that combines images and graphics with written text as well as sound and movement on screen. Moreover, the whole notion of 'authoring' has changed in the way texts are 'mashed' or hybrid texts created. As shown by Susan's text, the facilities of Web 2.0 have further changed the possibilities of students' writing and text production. Her digital narrative uploaded onto a wiki was carefully designed to engage the audience who could respond with text, images, or video.

For students to produce multimodal texts they need to consider and understand features of design such as composition, use of text, and image or graphics – including aspects such as color, size, medium, angles, placement on screen – and the way these are appropriate for a specific audience. It is significant that other researchers have been investigating design as integral to literacy pedagogy (e.g., Kalantzis and Cope, 2005; Healy, 2008).

Implications for literacy education are for teachers to realize that the teaching of writing is much more diverse with the potential for even young students to produce sophisticated products. Teachers need to demonstrate the structures and styles of genres that can be produced as digital texts, for example podcasts, vodcasts, wikis, blogs, and digital narratives. These are able to be augmented with photos, graphics, video, and sound. Thus design is an important aspect of writing and creating. A challenge for teachers is to consider how the use of design can be integrated with the teaching of writing while essential skills of language, grammar, and spelling are maintained.

The Holistic Potential of New Literacy Practices

While considering the differences in both reading on screen and reading print-based texts, reading and writing frequently occur together and are interdependent. As with the scenario of Susan, students are able to research and read information and then apply their learning by producing a response in a digital format. Nor is it sensible to separate the technical, functional processes of reading or writing on screen from the social practices that accompany these processes. The tasks will often involve collaboration and discussion between teachers and students as well as between students. Students are motivated to exchange information and to show their products to peers. This participatory culture is enabled by digital technology and reflects the sharing and exchange of information that occurs now in the wider society.

Thus literacy in a multimodal, digital environment has the potential to be holistic with an interdependency and fluidity between language and literacy functions. **Figure 1** depicts the process of reading and writing in classroom contexts where students work with traditional print-based texts and digital texts. Students can be required to read and write both print and digital texts and will therefore be interacting with a variety of modes. Reading and writing occur within a particular social context and for a specific purpose. They are often interrelated with reading leading to a writing task that may involve the design and production of a multimodal text or digital product for an audience.

The diagram in **Figure 1** shows that reading and writing with print and digital texts are interchangeable resources within classrooms. Making and communicating meaning are still the core purpose of literacy; however, reading and writing have the potential to be communicated through and with a variety of modes. Along with the interaction between modes of written texts, image, sound, and movement there is often interaction between students in this environment so there is an interrelationship between language and literacy activities. Oral language, thinking, and problem solving is an important factor as students plan, investigate, and collaborate to interpret or produce digital texts.

The technologies related to Web 2.0 along with the facilities of touch pad devices ensure the interrelatedness of reading and writing. These often occur along with the viewing and posting of images, the blending of sound, and the constant interchange and connecting of messages. Over a decade ago, emails revolutionized communication, taking over from letter writing, particularly for adults in the workplace. Communication through social networking has taken over from emails for many are being used in the commercial world. In such communication we are reading, writing, and responding asynchronously, although features of new technologies such as *SKYPE* and *Face Time* allow for synchronous communication through oral language, image, and gesture.

We do not know how such processing of messages and texts is affecting the way children learn or if the processes involved in

Figure 1 The holistic potential of new literacy practices. Source: Walsh, M., 2011. Multimodal Literacy: Researching Classroom Practice. PETAA, Newtown, p. 13.

activities such as texting, blogging, or communicating online are developing different cognitive abilities than those required for reading and writing traditional print-based texts. Gee's research (2003) on video gaming suggests that the procedures involved offer cognitive advantages with intricate literacy and learning opportunities. The touch features of recent products rely much more on gestural, spatial, and kinaesthetic movements that need further investigation in the way the embodied nature of this processing is affecting cognitive processes.

These unknowns are challenges for education. The study previously referred to (Bearne et al., 2007) on reading screens showed that while students were able to apply aspects of comprehension to obtain screen-based information it was "orchestrating the different modes to make meaning" (p. 20) that was seen as a different process that could not be assessed in the same way as the assessment of reading print-based texts. This is similar to Lemke's description of the 'multiplicative' (Lemke, 1998) effect that occurs when several modes are processed. A further study by Bearne and Wolstencroft (2007) demonstrated ways of teachers programming and assessing writing through students' multimodal texts. Bearne and Wolstencroft's work and classroom research in Sydney, Australia (Walsh, 2006, 2008, 2009, 2010) has emphasized how students need to understand the meaning-making potential of different modes, particularly the relationship between words and images, in reading, writing, and producing multimodal texts. Recent research by Walsh and Simpson (2013, 2014; Simpson and Walsh, 2014) shows how we need to distinguish between the technical skills of using digital technologies and the cognitive processes of interpreting and communicating meaning. To offset an overemphasis on technical skills, educators and researchers need to focus on using technologies together with a metaunderstanding of technology, particularly the way separate and multiple modes impact on meaning making.

Conclusion

The scenario at the start of this article demonstrates the way digital technology can allow communication to occur in a holistic, meaningful way. The implications of this discussion are that reading and writing with twenty-first century texts requires the processing of multiple modes and multiple reading pathways. Yet educational policy and curriculum documents are still based on theories of teaching reading and writing with print-based texts. Standardized national testing is currently based on traditional print-based literacy although there is a recognition of the importance of multimodal literacy in the move toward online testing, such as those developed in the PISA assessments (OECD, 2011). Issues of access and equity complicate attempts to develop curricula that encompass the potential of digital communication. Teachers need to adapt pedagogy so that, while they are teaching traditional skills of decoding and meaning making, they understand and examine the way different modes, especially visual, can engage students in meaning making. Similarly, writing in contemporary contexts requires further skills of design and production. New ways of programming and assessment are needed.

In this article I have raised some of the implications of changes in digital communication for literacy education. An examination of differences and similarities in reading and writing with print-based texts compared with multimodal texts has shown that, while multiple modes may need to be processed for reading and writing screen-based texts, meaning making is still the main purpose of communication. The

facilities of new technologies offer the potential for dynamic literacy learning. However, it is not the technology itself that will create a vibrant, engaging learning environment but the way teachers plan and structure literacy education. The future can be exciting for literacy in twenty-first century schools.

Literary and Philosophical Utopian Thought

Published by Elsevier Ltd.

Abstract

This article surveys *imagined*, i.e., fictional, societies that have speculated on solutions to the problems that humans face when they live together in population centers. It examines the myth of the Golden Age in the ancient world that gave rise to speculation about how to best organize society. It examines how major cultural shifts, such as the age of exploration, the Protestant Reformation, and Industrial Revolution, led authors to imagine how to stimulate reform and facilitate well-being and social justice in the modern era. Finally, the totalitarian dangers of utopian thinking are considered.

Literary and Philosophical Utopian Thought

Utopian literature envisions fictional societies in which human conflict and deprivation have been resolved by speculative rearrangement of existing political, cultural, and economic arrangements. Some examples of utopian speculation have been written with the explicit goal of popularizing such rearrangements of power, social norms, and distribution of resources in the real world. Other ideal fictional worlds have arisen as authors pursued their own curiosity, but subsequently captured the public imagination and sparked social and political reform movements. This was the case with Edward Bellamy's *Looking Backward* (1888), which was translated into dozens of languages and was so popular that by 1900 only *Uncle Tom's Cabin* had sold more copies.

While there are Asian and Middle Eastern literary works depicting idyllic states of human existence, these are dreams, fantasies, or descriptions of consciousness beyond the earthly plane, not political or philosophical tracts. It is well accepted that utopian literature as a genre has predominantly flourished in the West (Manuel and Manuel, 1979).

A combination of the Judeo-Christian paradise myth of the Garden of Eden and the afterlife, political writings of Hellenic antiquity, and the reform impetus of the Protestant Reformation have offered fertile ground for description of an improved, even perfected society, attainable *without* supernatural intervention or altered states of consciousness.

The Greeks wrote about a better future based on human reason and effort; Hebrew prophets theorized about a better future based on right action; and utopian thought and utopian social experiments have been influenced by these two ancient cultural sources. Post-Renaissance utopian thinking builds on the idea of progress (Bury, 1920/1932/1955) or inexorable scientific advancement and employs the idea of the future as an improvement on the present because of rational human efforts and technological advancements.

The Myth of the Golden Age

The first task of identifying and analyzing utopian treatises is to discern what they are not. In many cultures, societies, religions, and cosmogonies, but most prevalently in Judeo-Christian and Hellenic cultures, there exist myths of a distant past when humankind lived in a primitive state, free of trouble, want, or conflict. Manuel and Manuel call this idea of paradise "the deepest archaeological layer of Western utopia" (Manuel and Manuel, op. cit., p. 33).

The earliest known account of an ideal society occurs in a Sumerian epic poem of the fourth millenium BC in which Enmerkar, son of the sun god Utu, rules the orderly city of Erech (variously referred to as Uruk) (Langdon, 1915).

The University of Pennsylvania Museum of Archaeology and Anthropology houses some 30 000 clay tablets dating to 2900–500 BC inscribed in Sumerian and Akkadian cuneiform excavated in the late nineteenth century in Nippur (present-day Iraq). One of these describes a blissful and peaceful era before humans knew fear and before the 'confusion of tongues' (similar to the story of the Tower of Babel in Genesis 11, pp. 1–9) (Kramer, 1968):

In those days there was no snake, there was no scorpion, there was no hyena
There was no lion, there was no wild dog, no wolf
There was no fear, no terror
Man had no rival.
In those days the land Shubur (East), the place of plenty, of righteous decrees
Harmony-tongued Sumer (South), the great land of the 'decrees of princeship,'
Uri (North), the land having all that is needful
The land Martu (West), resting in security
The whole universe, the people in unison
To Enlil in one tongue gave praise.

Subsequent myths from many cultures describe an ancient state of complete fulfillment and harmony in which humans are totally satisfied by the abundance provided by nature, are free from disease, do not quarrel, and are released from the need for grinding drudgery to survive. In such a state, there is no reason for war or oppression. The natural order flows from a divine source and is just and gentle. Such myths of an idea, happy time, and place fall into three categories: Edenic human states (before sin or corruption), the reward of a life after corporeal life, and the domain of Gods (not human societies at all). Unlike utopian literature that followed, these accounts are not social commentaries or proposals for solutions

to problems; they constitute yearning for something before this era or beyond the terrestrial world.

Roots of Utopian Thinking in the Myth of the Golden Age

These legends of the earliest stage of humanity, such as the Biblical Garden of Eden, appear in myriad cultures. The Greek poet Hesiod, around the eighth century BC, in his compilation of mythological traditions (the poem *Works and Days*), explains that, prior to his present era, there were four progressively more perfect epochs, the oldest of which was the Golden Age (Hesiod, 1914). Plutarch, the Greek historian and biographer of the first century AD, also made reference to a blissful past of humanity. That Hesiod, Plato, and other Greek thinkers see the world disintegrating and becoming tainted and increasingly dysfunctional is consistent with Classical thinking that the world starts as perfect (utopian) and degenerates over time.

What Hesiod's and the Judeo-Christian story of Eden share is that in both, knowledge disrupts perfection: the tree of knowledge in the case of Eden and Pandora's Box in the case of Hesiod. Perfection is final and complete, while the introduction of knowledge changes the social order. Closed societies are suspicious of outside influences that introduce new knowledge and generate dissatisfaction with the status quo and the impetus for reform. It is a common characteristic of literary utopias that they are frequently located on isolated islands or distant planets, or in the distant future – far removed from dissenters or innovators.

Virgil's *Georgics* (29 BC) was modeled on Hesiod's *Works and Days* and also contemplated the characteristics of an ideal society. It describes the consequences of humanity's alteration of nature. Subsequent utopias have shared this environmental theme. Ecological utopias decry a perceived widening gap between the modern way of living that destroys nature and preagricultural or early agrarian society thought to be more in harmony with nature.

Ovid's *Metamorphoses* (AD 7) describes a past era when, because nature and reason were synchronized, human beings were naturally virtuous:

> The Golden Age was first; when Man, yet new,
> No rule but uncorrupted Reason knew:
> And, with a native bent, did good pursue.
> Unforc'd by punishment, un-aw'd by fear.
> His words were simple, and his soul sincere;
> Needless was written law, where none opprest:
> The law of Man was written in his breast.

As well attempting to assert timeless principles of a proposed ideal society, many works of utopian literature reflect the sensibilities and concerns of the era in which they were written. Some researchers regard Hesiod's *Works and Days* as a reaction to economic crisis in Greece at the time (Austin and Vidal-Naquet, 1977). This crisis stimulated colonial expeditions to find new lands of abundance and ease of living – the sorts of mythical places described in western Golden Age literature. Golden Age myths were so powerful that they impressed themselves on the Western persona with profound historical consequences. The cultural belief in the existence of a better time in a better place introduced a restlessness that drove succeeding generations to search for different lands where abundance and ease of life were believed to prevail.

Utopian Treatises of Antiquity

The earliest known utopian text that is truly a political treatise is *The Republic*, written by the Greek philosopher Plato around 380 BC. Part conversation, part fictional depiction, and part educational policy proposal, it slotted citizens into a rigid class structure of 'gold,' 'silver,' 'bronze,' and 'iron' vocational and social classes. The gold citizens were to be trained in a rigorous (five-decade long) educational program to serve as benign oligarchs or 'philosopher-kings.' Their wise leadership would supposedly eliminate poverty and deprivation through fairly distributed resources. However, Plato does not include details of the economic system or explain how the transition to his proposed society will occur.

Lack of explanation of how the transition is to occur is a common omission of utopian proposals. Many fictional utopias rely on the device of placing their imagined society in the remote future or past or on an undiscovered island to avoid this problem.

Approximately two generations later, a different work entitled *The Republic* was written in deliberate opposition to Plato's. The work of the same title was by Zeno, the founder of Stoic philosophy. Although it has not survived, it was his most admired work and is best understood in contrast to Plato's *Republic*. In Plato's society the wise citizen rules the lower classes, reflecting an aristocratic, oligarchic perspective, in which the subordination of lower classes to the rulers is central to the ideal arrangement of society. Zeno's ideal society, in contrast, contains *only* wise citizens and they are subjected to very little authority, making Zeno's work an early expression of libertarian ideas. Other striking aspects of the work are that the author opposed money even for the purposes of trade, but regarded women as property that should be held in common.

Another utopian work of antiquity was written by Euhemerus approximately a century after Plato wrote *The Republic*. Only fragments of the *Sacred History* exist, but from references to it by later historians, we know that it is a travelogue to an Arabian island, Panchaea, where diverse ethnic groups coexist peacefully and where rational and consistent rules underpin the political system. It too draws on the Hellenic tradition of a primordial era of happiness, before Pandora was tricked into unleashing a box of sins and suffering upon humanity.

The last notable work written before the fall of Rome that overlaps with the utopian genre is *On the City of God* by Augustine, 354–430 CE (Augustine of Hippo, 426/1998). It expounds on the superiority of Christian beliefs over pagan worship during times of adversity. Augustine was the son of a pagan. However, while studying in Africa to become a rhetorician he plunged into a turmoil of philosophical doubt in search of truth and famously converted to Christianity. As Hesiod's *Works and Days* was written in times of crisis in Greece, so was Augustine's work a response to the coming fall of Rome. The year 410 was a pivotal moment in Western history; the Vandals, under the command of Alaric, captured the city of

Rome. It is the first work that pits the state versus religion in a political treatise, arguing that in a struggle between two overlapping cities, one earthly and one heavenly, worship of the one Christian god should take precedence and worldly and political stability and prosperity would follow.

This work is followed by a thousand years of silence on the subject of how to imagine an improved or ideal society given mundane realities. Readers might draw the conclusion that people were too distracted with mere survival to contemplate an ideal society, or that whatever significant texts were written have been lost. Sociologists would assert that the very idea of solving social problems would have been entirely alien to the medieval mind. Though there are Renaissance writings on making human society better and more just, the acknowledgment of social problems as caused by human collective action and the idea of their solvability did not arise until the nineteenth century (Rubington and Weinberg, 2003).

Non-Western 'Utopianism'

In ancient China, utopian elements appeared in legalist, neo-Confucian, and Taoist thought. Confucius wrote about *Datong* ('the Great Unity'); *Taiping* was the term he gave to the most advanced stage of society. Another Chinese utopian conception occurs in *The Peach Blossom Spring*, a poem by T'ao Yüan Ming (365–427) about a pacific agrarian society.

Far more frequently than Eastern literature, Western utopian writing has the goal of presenting an alternative to the status quo and thereby nudging society toward improvements. And it has actually produced a plethora of intentional communities that directly affected western society and history and indirectly influenced non-western societies.

Depicting an imaginary paradise of self-indulgence, *The Peach Blossom Spring* (like the medieval poem *The Land of Cockaigne or* Cokaygne) is escapist fantasy without a proposed program for bringing about social justice.

Furthermore, the Hindu concept of *moksha* and the Buddhist concept of *nirvana* cannot be thought of as utopian (in the sense of offering a model for terrestrial society) because they do not describe a potential future, but a state of mind – a belief that if humans practice meditation to escape a continuous stream of nagging thoughts and desires, they can attain an enlightenment that leads to exit from the cycle of life and death. This concept is about individual enlightenment while true utopia literature envisions shifts in culture and political organization that will move the society overall to an ideal state.

There are examples of non-Western utopian writing that contradict the convention that utopian literature is solely Western. These include Li Ju-Chen's *Flowers in the Mirror* (1828) advocating rights for women, Kang Youwei's *DaT'ung Shu* (1935) advocating world unity, as well as African utopias and dystopias such as Bessie Head's *When Rain Clouds Gather* (1969), Ali A. Mazrui's *The Trial of Christopher Okigbo* (1971), Buchi Emechta's *The Rape of Shavi* (1983), Wole Soyinka's *Seasons of Anomy* (1973), and Ben Okri's *Astonishing the Gods* (1995), These examples of non-Western utopian literature all draw on Western intellectual history, starting with the appropriation of the literary genre of the novel (a Western literary innovation) to convey their ideas.

One towering counterexample is *On the Perfect State*, written by one of Islam's most renowned philosophers, Abū Nasr Muhammad bin al-Farakh al-Fārābi (known in European medieval texts as known in medieval Latin texts as Alfarabius or Avennasar) around AD 1000. See Attempted Utopias and Intentional Communities for more discussion of the impact of the writing of al-Fārābi. The treatise by the logician and cosmologist of in Damascus bears a strong relationship to *The Republic* of Plato in that it touts the discipline of philosophy as the path for discovering the correct views about free will and how to live a morally respectable and fulfilling earthly life, and that philosophers ought to be the sovereigns of the perfect state (Al-Farabi, 1985).

Early Renaissance Utopian Literature

Beginning in the fourteenth century, the European age of exploration was partially driven by a vision of unspoiled and beautiful new lands to explore. More's *Utopia* and Bacon's *The New Atlantis* were written during this era of discovery and embody the excitement of encountering new, unspoiled worlds – tabulae rasae for fresh new attempts at human civilization.

Thomas More was an early Renaissance humanist who celebrated reason and its power to create a rational and just society in his work *Utopia*, published in Latin in 1516 and translated into English in 1551. More may have been inspired by the possibilities of creating new societies in the New World. He describes a fictional island in the Atlantic Ocean in proximity to the Americas.

The title of More's novel is pivotal to understanding the utopian literary and philosophical tradition. The etymology of More's invented title is Greek: οὐ, meaning 'not' plus τόπος, 'place.' However, εὖ also means 'good.' Therefore 'eutopia/utopia' means 'good place' as well as 'no place' and signifies a double meaning of an ideal that is unattainable. Therefore, the idea of the impossibility of a perfect society is encoded into the very name of the genre. In common parlance, people will refer to an impossible or unrealistic proposal as 'utopian.' In this sense, the term emphasizes not the perfection but the naïveté of such projects. In fact, critics disagree as to whether the tone of More's travelogue and description is satirical or an earnest proposal for a society that values religious tolerance.

Friedrich Engels (1880/1970) wrote extensively on the significance of Thomas More's *Utopia*, noting that More was a contemporary witness to the emergence of the capitalist categories of bourgeoisie and proletariat emerging from a feudal society. The assertion of that More, a scion of London artisans, sympathized with the peasant masses being driven from their land and livelihoods and that he invented a way out of their wretched state in the travelogue of *A Fruitful and Pleasant Worke of the Best State of a PubliqueWeale, and of the NeweYle Called Utopia* (1516). More's fictional solution was that extended families of craftsmen cooperated and controlled the means of production of goods. Though he did not live to see this manifested in Soviet socialism, Engels saw More's solution as a precursor to cooperative villages.

In *Utopia*, More emphasizes social order, conformity, meaningful work, economic egalitarianism, and religious tolerance. However, in his own life, More was a devout Catholic who persecuted Protestants and burned the books of Martin Luther and William Tyndale. Six Protestants were burned at the stake for heresy during More's chancellorship and he is thought to have played a role in the burning of Tyndale. Some claim he advocated the extermination of Protestants.

This kind of moral dissonance was not uncommon in utopian thought. The impulse to design a society around one, or a small number of unifying principles can be oppressive. The goal of instilling order often takes precedence over more subtle and complex values like individual rights. Views and behaviors other than those dictated by the rules of society and those of the majority may introduce dissatisfaction and upset the smooth running of society. In *The Republic*, Plato's suggestion for how to manage dissenters and poets is that they be exiled. Utopianism tends toward a conformist majoritarian view of society rather than upholding the constitutionalist value of protecting the free speech of citizens because of the value of dissent in correcting and reforming society.

Francis Bacon was called the father of the scientific method by Voltaire, and Thomas Jefferson considered him one of the three greatest men to have ever lived (along with Locke and Newton) (Jefferson, 1789). His utopian *New Atlantis* (1624) depicted a society attuned to the possibilities of rational, organized, intentional, scientific method and places the research university at the center of the imagined society. Both More and Bacon place their utopias on an island near the Americas. Like More, Bacon was clearly inspired by the possibilities of creating new societies in the New World; in fact, he was influential in creating the Virginia and Carolinas colonies. Unlike *Utopia*, *New Atlantis* is technocratic – based on science and invention. In this sense it was an anticipation of modernity while *Utopia* was premodern.

Contrasting the 'knowledge for its own sake' approach of ancient Greek inquiry, Bacon was an advocate for investigating nature to gain knowledge that would materially benefit humankind. This is a fundamental difference between the Classical and Renaissance perspective on the world. Bacon called for a "progeny of inventions, which shall … subdue our needs and miseries." Because of this he is sometimes called the father of the industrial revolution. *New Atlantis* was secularly subversive. Its aim was to substitute spiritual salvation by serving God with a well-run state dedicated to material well-being created by and for humans. It is a quintessential example of the idea of progress, as Bury examines it.

The story reveals the Judeo-Christian roots of some utopian thinking. The name of Bacon's fictional island is Bensalem, a Hebrew word that can be translated as either 'Son of Peace' or 'Son of Jerusalem.' The primary educational or research institution on the island is called 'Solomon's House' ('…denominate of the king of the Hebrews'). It is a description of what eventually came to be the modern research university and ultimately inspired the creation of 'The Royal Society.' A significant character is Joabin the Jew who claims that the Bensalemites are descendants of Abraham and their laws came from Moses. Numerous symbols in the story associate Bensalem with God's 'Chosen People' and a New Jerusalem, images that also inform the Pilgrim and Puritan experiments in New England.

The Idea of Progress

Modern utopian thought coincided with Renaissance critical thinking which produced the Reformation and Scientific Revolution which evolved into the Enlightenment or the Age of Reason. The sixteenth through twentieth centuries fostered the concept that human beings could harness effort and reason to create just societies; that is they could progress toward a better life in the corporeal world rather than wait for the better life in the imagined world to come. Prior to the Enlightenment, people thought of suffering and deprivation as part and parcel of their brief life in preparation for the world to come. The forward-looking, human-centered, and optimistic perspective of the Enlightenment constitutes an important break with the backward-looking that any ideal or uncorrupted collective state was lost or hopelessly buried in past time.

Utopianism from the Renaissance on is forward-thinking. It harnesses rationality into practical application and reveals a secular mind-set even when advanced by religious thinkers. For Protestants in particular, access to the 'world to come' depends on behavior in this world – not only as individuals but as organized societies.

Influenced by Plato's idea of a benign oligarchy, Tommaso Campanella's *City of the Sun* (1601) depicts a unified, peaceful world governed by a theocratic monarchy. He advocates both communism (within which children and women are shared, along with inanimate property) and eugenics to keep society fit and healthy. Campanella anticipated Dewey's 'Learning by Doing' with 'Learning by Observing.' Society itself was the classroom and the walls of the buildings were like a huge illustrated encyclopedia, featuring murals and alphabets. Campanella's conception of the inhabited environment as a pedagogical tool inspired Lenin's propaganda strategy. As totalitarian as Campanella's vision may seem in retrospect, it dramatizes an organized social system to maximize human potential.

Louis-Sébastien Mercier published *The Year 2440: A Dream If Ever There Was One* in 1770. Mercier's eighteenth-century hero falls asleep and wakes more than 500 years later where he sees the contrast between the decay of eighteenth-century Paris and Paris of 2440. Public space is accessible and elegant; the justice system is fair; clothing is comfortable and practical; medical care is based on science and available to all. There are no monks, priests, prostitutes, beggars, slavery, taxes, guilds, armies, or arbitrary arrest. But Mercier's utopia also gets rid of foreign trade, coffee, tea, dancing teachers, and pastry chefs, perhaps because they are purveyors of temptation and emblematic of decadence. Anticipating twentieth-century dictators and reflecting Plato's dislike of poets, Mercier's Paris also abjures 'useless' or 'immoral' literature. This illustrates a commonality of utopian writers – raising personal affinity or distaste to the level of ideology and principle, embodied in the idea that if society merely rids itself of pastry chefs all will be well.

Utopias in the Industrial Age

Equality; or, A History of Lithconia (1802) was the first American utopian novel. Its author is unknown. It depicted an island with a liberal attitude toward sex: the author believed that

the institution of marriage as the only legitimate way to enjoy sex is what caused prostitution. In Lithconia, children were the property of the state. Religion was criticized for meddling in intimate relations. Leisure was more important than work – one worked to gain sustenance, one had leisure in order to live: "…there was no money in the country…lands are in common…labor is a duty required of every citizen… and that duty being performed the remainder of his time is his own…".

Three Hundred Years Hence (1836) by American writer and scientist Mary Griffith was the first utopian fiction written by an American woman and the first to use the future to depict an improved social order. The hero falls asleep and wakes up in the Utopian states of Pennsylvania, New Jersey, and New York 'three hundred years hence.'

Étienne Cabet, the founder of the *Icarian* Movement (see 'Utopian Practice'), wrote *Travel and Adventures of Lord William Carisdall in Icaria* in 1840. It depicted an ideal society in which a democratically elected governing body controlled all economic activity and closely supervised social life. The book's popularity inspired him to establish his utopian movement.

In John Macnie's *The Diothas; or, A Far Look Ahead* (1883), the narrator wakes up in the ninety-sixth century where he finds himself in a New York-like megalopolis. The book predicts paved roads with white lines down the center to separate traffic, a global telephone network, recorded university lectures, electric cars, computers and computer graphics as well as rooftop gardens on public and private buildings. The genders are equal and women have invented television and motion pictures. Society is quasi-socialist.

Like the European age of Exploration, the great emigrations to the United States in the late nineteenth and early twentieth centuries as well as the subsequent migrations to the American West are manifestations of the search for a better life that shares something with the myth of agrarian peace and plenty. The utopian/Golden Age mind-set has historical consequences that are also described in "Attempted Utopias and Intentional Communities."

In the nineteenth century, utopian literature looked to rationality as a way to reshape society. Utopian works also gave voice to the perception that social disruption following the industrial revolution was created and caused by the rise of capitalism and profit motive as an organizing principle of society. These works are often grouped in a greater 'utopian socialist' movement, due to their shared characteristics: an egalitarian distribution of goods, frequently with the total abolition of money, and citizens only doing work which they enjoy and which is for the common good, leaving them ample time for the cultivation of the arts and sciences.

Along with myriad reform movements, the nineteenth century saw an increase in utopian works of fiction, many expressing the belief that social disruption was caused by the rise of capitalism and the profit motive as an organizing principle of society. These works are often grouped in a greater 'utopian socialist' movement, due to their shared characteristics: an egalitarian distribution of goods, the frequent abolition of money, and citizens only doing work that they enjoy and that is for the common good, leaving them with ample time for the cultivation of the arts and sciences.

As in Macnie's *The Diothas* and Mercier's view of a future utopian Paris, Bellamy's vision of a socialist England (and Europe) is told through the device of a citizen of England in the late nineteenth century who sleeps for more than a century and wakes up in a world with equally distributed wealth, in which there is no currency. Citizens merely receive the food, clothing, housing, education, etc. that they need.

Though they are offering an alternative vision of the future, utopian novels such as Bellamy's have used the device of a protagonist (contemporary with the reader) looking backward to the troubled present from a future point when most or all problems have been solved. Yet, the navigation to that future point of social and political transformation is seldom explained. In *Looking Backward*, the genesis of the socialist utopia in which all private property has been nationalized is simply described as the peaceful merging of monopolistic business concerns with the state so that 'the nation is the sole employer and capitalist' in contrast to the turmoil of Soviet and Maoist state socialism that the novel anticipated.

The World a Department Store: A Story of Life under a Cooperative System (1900) by Bradford C. Peck is another example of a protagonist going to sleep and waking up in the future. The author, Peck, was a self-made millionaire who became an advocate of a cooperative society as a palliative to the excesses of capitalism following the panic of 1893 and subsequent economic depression. He admired Bellamy's *Looking Backward* and Henry George's *Progress and Poverty*. The protagonist Percy Brantford (a play on the author's name) is a successful businessman who, after taking an overdose of a sleeping potion, lapses into a coma and wakes up 25 years later. He finds that his hometown has become Cooperative City, and has eliminated poverty, slums, and litter.

Ionia: Land of Wise Men and Fair Women (1898) by Alexander Craig describes a utopian society in the Himalayas in which electricity drawn from the earth's magnetic field supplies all energy needs. Land is owned by the state and leased to businesses and individuals. Poverty and debt have been eradicated and control of pollution and recycling of waste is paramount. The average lifespan is over 100 – twice the lifespan of Europe at the time.

Parallels to Ionia in James Hilton's novel *Lost Horizon* (1933) are too numerous to ignore; interestingly Craig wrote his book during the severe economic depression of 1893–1898 while Hilton wrote his at the outset of the Great Depression of the 1930s. Crisis, whether economic, social, or political, seems to stimulate the imagination to invoke a better way of life.

Earth Revisited (1893) by Byron Brooks also projects its nineteenth-century protagonist into the future where he encounters communal food production, solar power, electric cars, color photography, and a reclamation project that turns the entire Sahara desert into rich farmland. It also describes a juvenile justice system authorized to remove children from unfit parents.

The Human Drift (1894) by King Camp Gillette (the founder of the Gillette razor blade company) advocated a single publicly owned corporation that would control all economic activity (a variation on *Looking Backward*, in which the state subsumes monopolies). At the time the United States had 60 million citizens and the book proposed they all be concentrated in one giant metropolis built over Niagara Falls where the first large electrical generating facilities were being constructed by Tesla and Westinghouse. Gillette thought the city could absorb an additional 30 million people of future

population growth. Intensive agriculture would be in proximity to the city limits. The rest of the continent would revert back to nature. Gillette was a business tycoon who believed that the business magnate would be the natural leader of social reform, because of his rationality, his managerial ability, and his understanding of the power of capital.

Aristopia: A Romance-History of the New World (1895) by Castello Holford is a 'what if?' utopian speculation. The novel asks, "What if the founding of the United States had occurred under different conditions? Would American society have developed in a superior way?"

In His Steps: What Would Jesus Do? (1897) by Congregationalist Minister Charles Sheldon is not about personal redemption but rather about moral choices leading to or avoiding poverty and deprivation. The protagonist Rev. Henry Maxwell challenges his congregation to not do anything for an entire year without asking: "What Would Jesus Do?" Though overtly religious, it is based in the modern and secular ideas of rationality and personal responsibility.

The meaning of 'utopia' as 'ou-topia' or 'noplace' has had far-reaching resonance in the titles and themes of novels written hundreds of years after More provided the genre with its label. *The News from Nowhere* (1890) by William Morris presented a more libertarian (non-state) socialism in which there was no private property, big cities, or state authority. There was also no money, divorce, courts, prisons, or class system. Samuel Butler titled his satire and proto-dystopia *Erewhon*, which is an anagram (or nearly backward spelling) of 'nowhere.'

The Year 3000: A Dream was published in 1897 by Italian anthropologist Paolo Mantegazza. It is a work of utopian early science fiction in which a couple on their honeymoon ('mating union') in the capital of the United Planetary States visit a socialist utopia with airplanes, artificial intelligence, CAT scans, and credit cards as well as serious debates about divorce, abortion, and euthanasia. Mantegazza also predicted a unified Europe, world peace, and the elimination of disease.

Other works in this vein include *A Traveler from Altruria* by William Dean Howells (1892–93), which criticized the robber baron capitalism of the age. Altruria is an isolated island in which life is based on altruism (hence its name). *A Modern Utopia* (1905) by H.G. Wells is a modern takeoff on Plato's *Republic* in that benign Samurai on a different planet (a kind of cosmic island) have found a much better way to live.

Less frequently, utopias have also been imagined on the opposite side of the political spectrum. For example, Robert A. Heinlein's *The Moon Is a Harsh Mistress* portrays an individualistic and libertarian utopia. Capitalist utopias of this sort are generally based on free-market economies, in which the presupposition is that private enterprise and personal initiative without an institution of coercion, government, provides the greatest opportunity for achievement and progress of both the individual and society as a whole. 'Galt's Gulch' in Ayn Rand's *Atlas Shrugged* is another presentation of a libertarian and individualistic utopia.

The Soviet writer Ivan Efremov produced during the 'Thaw' period the science-fiction utopia in which a united humanity communicates with a galaxy-wide Great Circle and develops its technology and culture within a social framework characterized by vigorous competition between alternative philosophies.

One example of utopian thought that inspired a massive social movement was Theodore Herzl's utopian novel *Old New Land* in which Herzl, the founder of Political Zionism, painted a utopian vision to help sell the political idea of repatriating Israel as an attainable possibility.

Freeland: A Social Anticipation (1891) by Theodor Hertzka (the Austrian counterpart to Bellamy) was hugely successful throughout Europe and inspired a utopian movement of 1000 members in 24 chapters. A small group also tried to establish a utopian community based on Hertzka's work in Kenya but failed.

Ecological Utopias

William Henry Hudson was a naturalist who wrote *A Crystal Age* (1887), which describes a dystopian collapse of modern civilization as a prelude to a back-to-nature utopia.

In his final work *Island* (1963), Aldous Huxley depicts a gentle and doomed utopian, fictional island Pala. He uses the form of the novel to issue a warning about overpopulation, coercive politics, militarism, and mechanization, and highlights the destruction of the environment and the worship of science in contrast to Pala.

In the novelette *Rumfuddle* (1973), Jack Vance presents an inventive twist on the ecological utopia. His hero invents paratime travel and becomes effectively the ruler of earth by giving everyone their own alternate earth wilderness world as vacation retreats/suburbs without neighbors. However, he requires them to work during the week cleaning up the original earth and restoring its pristineness. A typical job is driving a bulldozer that shoves the detritus of industrial civilization through a portal into the oceans of a paratime garbage world.

Ecological planning is the central thrust of *Ecotopia: The Notebooks and Reports of William Weston* (1975) by Ernest Callenbach, in which the Pacific Northwest has seceded from the union to set up a new society. Callenbach subsequently wrote a prequel (1981) to better explain how Ecotopia had come to secede from the United States. Several fictional utopias, notably *Woman on the Edge of Time* (1976) by Marge Piercy, attend closely to environmental sustainability in the design of their society.

Feminist Utopias

Elizabeth Corbett's *New Amazonia: A Foretaste of the Future* (1889) envisions a successful suffragette movement that eventually produces a breed of 'Amazonians' who create a female utopian society. The book's female narrator wakes up in the year 2472 and finds that the Amazonians are vegetarians who use euthanasia to eliminate malformed and illegitimate children. Their economy is a version of state socialism and while men are allowed to live on the island, they are forbidden to hold public office.

Utopias have been used to explore whether gender is a societal construct or a hard-wired imperative. The fictional aliens in Mary Gentle's *Golden Witchbreed* (1985) start out as gender-neutral children and do not develop into men and women until puberty, and gender has no bearing on their social roles.

In contrast, Doris Lessing's *The Marriages Between Zones Three, Four and Five* (1980) suggests that men's and women's values are inherent to the sexes and cannot be changed, making compromise between them essential. In *My Own Utopia* (1961) by Elizabeth Mann Borghese, gender exists but is dependent upon age rather than sex; genderless children mature into women, some of whom subsequently become men.

Utopian single-gender worlds or single-sex societies have long been one of the primary ways to explore gender inequality in work. In speculative fiction, female-only worlds have been imagined to come about by the action of disease that wipes out men, along with the development of female parthenogenic reproduction. The resulting society is often shown to be utopian by feminist writers. Many influential feminist utopias of this sort were written in the 1970s: notably Joanna Russ's *The Female Man* (1975) and Suzy McKee Charnas's *Walk to the End of the World* (1974) and *Motherlines* (1981).

Utopias imagined by male authors have generally included equality between sexes, rather than separating them. Worlds without men have been portrayed almost exclusively by lesbian or feminist authors; their use of female-only worlds allows the exploration of female independence and freedom from patriarchy. The societies may not necessarily be lesbian, or sexual at all – a famous early example of a celibate, females-only utopia being *Herland* (1915) by Charlotte Perkins Gilman. This was followed by the sequel *With Her in Ourland* (1916).

Gilman had previously written a nonfeminist utopian novel *Moving the Mountain* (1911), which, similarly to Bradford Peck, moves its protagonist into the immediate (1940) rather than the distant future. This shorter term gambit demonstrates that the author wished to influence current society by showing it could achieve with imagination and political will. In the novel, by 1940, the United States had eliminated poverty and prostitution; had solved the labor problem, the color problem, and the sex problem; and had almost eliminated disease, accidents, and fires. Most people worked 4 h a day even though they only had to work 2 h a day to maintain themselves. Deforestation and soil erosion were in advanced stages of remediation. Tidal, wind, and solar power were the primary means of generating energy and the skies were filled with aircraft – a stunning vision for a book written in 1911.

Ambiguous Utopias and Dystopias

Focusing on a central problem in an attempt to eradicate it produces social distortion in the hypothetical society's treatment of other problems, such as the need for individuality and creative expression.

The Dispossessed (1974) by Ursula LeGuin is one of the few utopian novels that takes this balancing act into account. The novel is nuanced in that it touts a 'nonpropertarian' society, while simultaneously criticizing this egalitarian society for its isolation of people who are exceptional (principally the protagonist). *The Dispossessed* confronts the question of how to balance the social flattening of the fictional society of Anarres with the urge of the individual (the protagonist, Shevek) to fully explore his extraordinary talents. The main character of *The Dispossessed* is a mold-breaking physicist who is impeded in his work by his society's inability to balance the ideal of equality and the pursuit of the common good promoted by his imagination and need for solitude and the resources to conduct research.

Utopian literary thinking spawned other speculative fiction, most prominently that of dystopia, a subgenre that examines the totalitarian penumbra of utopian projects. Notable examples include *1984* by George Orwell (1949), *Brave New World* (1932) by Aldous Huxley, and *Anthem* (1938) by Ayn Rand. Very few earnest utopian novels have been written since the early 1970s; *The Dispossessed* (1974) by Ursula LeGuin is among the last.

Like fictional utopias, dystopias also depict the vision and planning necessary to bring the imagined society under one philosophical tent. However, in dystopian fiction, something has gone terribly wrong for some or all of the characters. For example, *Brave New World* is arguably utopian for nearly all of its characters. In the grand scheme of mechanized manufacturing applied to human reproduction, the citizens of London in 2540 feel included; their needs are met; they are provided with productive work, an ample supply of Soma (a mild tranquilizer), and attachment-free sex. However, the protagonist John the Savage cannot fit in or find sufficient meaning in its planned society and hangs himself at the end of the novel.

Walden Two is a novel written by behavioral psychologist B. F. Skinner. In 1948 when it was written, it was science fiction, since science-based methods for altering behavior did not yet exist. Such methods are now known as applied behavior analysis. The novel might seem utopian to some and terrifying to others because it relies on a rejection of free will. *Walden Two* embraces the proposition that the behavior of organisms, including humans, is absolutely determined by genetic and environmental variables and that systematically altering environmental variables can generate a sociocultural system that approximates utopia. The dark side of such a proposition can be seen in *A Clockwork Orange* (1962) by Anthony Burgess, in which juvenile delinquents are subjected to harsh conditioning to break them of their violent impulses or the brutal conformity of the scenes in Camazotz in *A Wrinkle in Time* by Madeleine, published in the same year.

The Truman Show (1998), a film directed by Peter Weir, depicts a utopia created for one man, the star of a reality television show, a utopia of which he is unwittingly the center. His town and his life are seemingly clean, happy, and prosperous, until he begins to suspect that his life is completely artificial. This underlines the idea that people must choose to join a community, no matter how idyllic, of their own free will.

One of the most chilling exposés of the dark side of the utopian impetus is the science fiction film *Serenity* (2005) written and directed by Joss Whedon. In the film, the central government wafts a tranquilizing gas into the environment of a newly colonized planet (to suppress their aggressive urges), only to find that some citizens exposed to it simply lose their will to live while others become hyperaggressive. Finding that it has created homicidal rapists and cannibals, it then exerts extreme control to keep the effects of the gas a secret.

An exploration of the dark side of utopia is Ursula LeGuin's short story *The Ones Who Walk Away from Omelas* (1973). A utopian city of peace and plenty is the main 'character' of the

story in which characters are simply used to dramatize the philosophical idea the story explores. In a kind of Taoist balance, the pleasant lives of the citizens require that a single child be held captive in filth and deprivation. What may be a utopia for some is dystopia for another. Citizens are informed of the trade-off when they reach the age of majority and may choose to stay or leave in the nearly ideal city.

The Totalitarian Impulse

Not surprisingly, most utopian novels fail to deal with problems faced in the contemporary, globalized, multicultural society we actually inhabit. For example, there are very few comprehensive speculative responses to racial discrimination or oppression of subordinate cultural groups in multiethnic or polylingual societies. The anti-Semitism of Fourier and Craig's utopias is the canary in the coal mine of a type of utopian thinking that prefers a homogeneous world free of dissenters, visionaries, or nonconformists.

One of the few mentions of racial strife occurs in LeGuin's *The Lathe of Heaven* (1971) in which the protagonist telekinetically dreams of solutions to problems in a world very like our own. His actualized dream to address racism makes inhabitants of the world undifferentiated by facial structure or pigmentation. Not surprisingly, the narrator and the characters perceive this as an unsatisfactory solution. Marge Piercy's *Woman on the Edge of Time* (1976) addresses racism through a combination of assigned rather than biological families and genetic engineering so that no character is 'white'; everyone has family members of various shades of brown.

Total control of society is vital to the idea of perfection or solution of *all* problems. Centralized and strong, though benign, authority is therefore a distinguishing characteristic of utopian literature. Plato's vision of the 'good society' is predicated on intolerance of disorder or dissent. For Plato, poets are corruptors of morality because they imitate reality rather than seeking ultimate truth. Artists deal with the world of imagination appearance and not absolute reality. They were to be banished from his imagined commonwealth. This begs the question 'Whose truth; whose reality?' Utopians often present their subjective intellectual predilections as objective truth and utopian intolerance for alternative visions of life have a long pedigree – with deadly consequences. Plato did not like other poets (he was a poet himself by any standard) so he wanted to banish poets. Plato most likely pictured himself as a philosopher-king so his 'utopia' had him in charge. Karl Popper went so far as to brand Plato as one of the antecedents of Fascism by quoting him:

> The greatest principle of all is that nobody, whether male or female, should be without a leader. Nor should the mind of anybody be habituated to letting him do anything at all on his own initiative; neither out of zeal, nor even playfully. But in war and in the midst of peace – to his leader he shall direct his eye and follow him faithfully. And even in the smallest matter he should stand under leadership. For example, he should get up, or move, or wash, or take his meals … only if he has been told to do so. In a word, he should teach his soul, by long habit, never to dream of acting independently, and to become utterly incapable of it.

Popper concludes that "Plato's political program, far from being morally superior to totalitarianism, is fundamentally identical with it" (Popper, 1965).

The Utopian Quandary

The island as a trope in utopian literature expresses poetically the nearly universal hope for new, undiscovered lands and social systems, but also dramatizes the degree of isolation and control such social orders may require. Both literary and attempted utopias depend on being cut off from the larger world. When pressed, the mouthpiece of Bellamy's *Looking Backward* admits to the visitor from the past that if the social utopia were to traffic with the as-yet unconverted portion of the world, the moneyless society could not survive. Only through segregation from other groups with different values and access to resources are such isolated utopias possible. As the world becomes more interconnected and interdependent, the thought experiments of fictional utopias become more valuable than ever, but such speculation must find a way to integrate order and justice with the variety of faiths, cultures, and norms that global society brings together.

Lithics and Archaeology

Jacques Pelegrin, Allée de l'Université, NANTERRE cedex, France

Abstract

In archaeology, 'lithics' refers to all stone artifacts fabricated by humans from the beginning of prehistory until the present time. Stone artifacts play a major role in the understanding of prehistory. They are the most abundant, and often the only, human-worked material preserved on prehistoric sites, and they retain traces informative of their fabrication and use. From an anthropological perspective, stone tool making is an essential criterion indicating human evolution. For the Paleolithic, and along with ceramics and metal for later periods, it is a fundamental source of information concerning past human societies' traditions and economy.

Historical Aspects

The Significance of Lithics in the Discovery of Prehistory

At the end of the sixteenth century, Mercati recognized the human origin of polished stone axes, which were previously believed to have been created by lightning bolts. In 1723, Jussieu compared stone axes to ethnographic objects from Canada and the Caribbean. Most notably, as early as the beginning of the nineteenth century, Thomsen classified objects from the Royal Museum of Copenhagen into three successive phases: Stone Age, Bronze Age, and Iron Age. In 1866, Lubbock divided the Stone Age into the Paleolithic, or knapped Stone Age, and Neolithic, or polished Stone Age. Meanwhile, the Stone Age, which encompassed all of humanity, remained undated until the development of absolute dating methods (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology).

However, the notion that stone tools were very ancient was suggested as early as the late eighteenth century when John Frere identified stone tools in association with the bones of pachyderms at Hoxne (Suffolk, England). Soon after, the first excavations of caves in France, Belgium, and England allowed for arguments of a great antiquity of humanity. In 1859, Boucher de Perthes, with support from British geologists, finally succeeded in convincing the scientific community of the existence of an ancient, properly 'antediluvian' epoch of humanity. He demonstrated that flint hand axes could be found *in situ* with the bones of extinct animals deep within gravel quarries in northern France. The idea of very early prehistoric humans equipped with only stone tools was born.

Lithics as a Criterion for the Definition of Early Humanity?

Chimpanzees, our closest primate relatives, can use natural objects as tools (stone hammers and anvils to break nuts) and even alter natural objects to make tools (removing leaves from twigs to capture termites or ants), but they do not fabricate stone tools in the wild (Berthelet and Chavaillon, 1993). The production of stone tools is thus a tempting criterion for distinguishing the earliest species of *Homo* (*Homo habilis*, *Homo rudolfensis*, etc.) from their ancestors and from other contemporary hominids, Australopithicenes, who became extinct between 3 and 1 million years ago. Unfortunately, this criterion remains putative since it is rare to find stone tools and early hominid fossils in direct association. There is as well no a priori reason to believe that some of the Australopithecines did not also make stone tools (Hovers and Braun, 2009). Currently, the oldest known assemblage of knapped stones, discovered by H. Roche at the site of Kada Gona in Ethiopia, and dated to at least 2.6 million years ago, already shows mastery of conchoïdal fracture (the basis of controlled stone knapping), perhaps indicating that stone tool technology had already existed for a considerable time (Roche et al., 2009).

The Role of Lithics in the Construction of a Prehistoric Chronology

Once the great antiquity of humankind was finally accepted, researchers put their efforts into developing a chronological classification of the Stone Age. After the first paleontological subdivisions of E. Lartet (1858; Cave Bear Epoch, Reindeer Epoch), classifications were based on stone tools, along with bone tools for more recent periods (G. de Mortillet in 1869, E. Piette in 1889, H. Breuil in 1912, and D. Peyrony in 1933). These classifications emphasized the most characteristic tools found in strata of different sites. Following a paleontogeological perspective, these tools were called 'index fossils.'

This procedure led to two excesses that sometimes persist in current research. First, these 'index fossils' were regarded as exclusively representative of distinct time periods and 'cultures,' which were believed to represent different human groups in an ethnic sense, following an overly simplistic historic schematization (*see* Ethnic Identity and Ethnicity in Archaeology). Much work has since been devoted to determining precise dates and geographic origins for these cultures and groups, which are seen to follow a rigid succession of 'evolutionary cycles' based on the appearance and disappearance of a few tool types. Second, these successive cultures, which were originally defined in France following the excavation of numerous stratified sites, were abusively extended to other European regions, thus masking the originality of archaeological data over broad areas.

A Slowly Developing Technological Perspective

As early as the nineteenth century, some archaeologists were becoming interested in what stone tools could tell us about the

daily activities of our ancestors. They asked a first, seemingly accessible, question: how were these tools made?

This question immediately led to attempts to reproduce stone tools, yet the results remained superficial due to poor experimental procedure and lack of rigor, according to L.L. Johnson (1978). Numerous prehistorians observed modern gunflint knappers at Meusnes, France, and Brandon, Suffolk, at the beginning of the twentieth century. However, an extreme production standardization, and exclusive use of iron tools, limited the utility of the comparison. Other prehistorians turned to early accounts of Native Americans manufacturing stone tools. However, many of the descriptions they consulted were second-hand, and thus too imprecise to be useful. Nonetheless, the record in the Spanish Codex of obsidian pressure debitage by the Aztecs permitted D. Crabtree in 1968, and then J.E. Clark in 1982, to successfully reproduce this production process.

Some prehistorians, such as J. Evans, were able to synthesize numerous observations of archaeological collections, ethnographic records, and their own knapping experiments. As a result, the three major knapping operations (shaping, debitage, and retouch) and several knapping techniques (direct, hard stone percussion; indirect 'punch' percussion; and pressure retouch) were recognized very early, at about 1870. The research of W.H. Holmes during the early twentieth century concerning the lithic production activities of ethnographic and prehistoric North Americans was also remarkably modern in its approach to and interpretation of technology.

Meanwhile, the functions of stone tools remained hypothetical except for a few objects such as polished axes and certain arrowheads, the form of which suggests their potential use. Lacking other methods for determining function, the principal categories of stone tools were named after their similarity of shape with traditional tools (e.g., scrapers, borers, and knives).

Recent Methodological Developments and Research Orientations

In conjunction with the genealogical perspective described above, early research was essentially aimed at identifying the major evolutionary stages of the Paleolithic cultures. It was not until the middle of the twentieth century that broader and more analytical perspectives were developed.

The Typotechnological Approach

During the 1950s, the French prehistorian François Bordes developed a method of studying and comparing assemblages of lithic artifacts, as opposed to single objects, which was both quantitative and qualitative. The technological understanding of the objects that he gained through personal knapping experience enriched the methodology he developed. While in the past it had been considered sufficient to discuss only the 'index fossils,' this new method entailed study of all the tools recovered from the site or the layer, as well as the technological processes by which they were made. The objective of this broader characterization of lithic industries was the identification of the conceptions of the prehistoric groups that produced them. This became the basis of what is referred to as the 'cultural' approach, which has since been subject to long debates. In particular, Bordes distinguished several different, contemporaneous 'facies' in the Late Mousterian of southwest France. He interpreted these as being representative of different human groups, with different technological traditions, occupying the same region at the same time (Bordes, 1950). L. Binford and S. Binford contested this interpretation, proposing instead that these different facies represented different functional, perhaps seasonal, activities. Other researchers have proposed that these facies could be chronological phases or that they reflect the differential availability of raw materials. None of these interpretations has received unanimous acceptance. In addition, F. Bordes' method of distinguishing tool types was rather intuitive; some authors, like H.L. Dibble, have suggested that several of these tool types actually represent different stages of use and resharpening of a single type of tool. Presently, economic and behavioral factors are proposed as accounting for at least some of the diversity of Mousterian assemblages (see Delagnes and Rendu, 2011; Kuhn, 1995).

Meanwhile, advances in computer technology that have allowed for more elaborate statistical analyses permitted H.L. Movius to confirm the reality of several tool types distinguished by F. Bordes and D. de Sonneville-Bordes, particularly for the Upper Paleolithic. The 'reality' and meaning of types, and the possible use of typological analysis continue to be debated.

The Paleoethnological Approach

André Leroi-Gourhan, a French contemporary of Bordes, implemented a paleoethnological approach to prehistoric human groups. This perspective stemmed from his more general studies of techniques in ethnographic contexts, following in the mid of the twentieth century a broad anthropological perspective (Leroi-Gourhan, 1993). Along with other members of his research team, his objective was to reconstruct the spatial dimensions of human activities, which are principally represented by the remains of their technological activities and the organization of the artifacts in relation to various structures (fireplaces, traces of huts or tents, etc.). Such spatial analysis could be performed only at those rare sites, like the famous 'Pincevent' in the Paris basin where occupation floors are well preserved. In addition, excavation techniques had to be modified from the primarily vertical, stratigraphic section approach that was well adapted to the chronological perspective described above, to a more horizontal approach to allow for exposure of contemporaneous objects on an occupation floor (*see* Survey and Excavation (Field Methods) in Archaeology). Under these conditions, this research objective led to two important methodological developments.

The first development was the systematic search for refits between broken objects, retouch flakes and the tool from which they originate, and between lithic items successively detached from their core. As sporadically shown since the nineteenth century, refitting makes it possible to detect disturbances within and between archaeological levels, and also to interpret certain archaeological structures and activity areas. In addition to better grasping the spatial and chronological relations between isolated objects, the method of refitting is increasingly

used to address behavioral and technological questions (Schurmans and De Bie, 2007).

The second development has been the emergence, in France and increasingly in the Anglo-Saxon world, of an approach that considers all lithic remains, including waste products of production, finished tools, as well as used and abandoned or broken tools, in terms of their technical process of production and use. This analysis, originally developed in ethnological research and the anthropology of techniques, following the inspiration of Marcel Mauss and André Leroi-Gourhan, is called the *chaîne opératoire* (operational sequence) approach (Schlanger, 2005; Soressi and Geneste, 2011). This sequence is composed of the succession of technical actions beginning with raw material acquisition and continuing to the abandonment of the manufactured tools. The detailed, empirical, and experimentally based analysis of this sequence, including its invariant and flexible moments, its constraints, and its choices, makes it possible to reconstruct, at least in part, the social, cognitive, economic, and environmental factors implicated in the transformation of naturally occurring materials into finished cultural products (Dobres and Hoffman, 1999; Inizan et al., 1999–2009).

The Processual Approach

Beginning in the 1960s, L. Binford and other American archaeologists developed the theoretical approach called 'processual archaeology.' According to this approach, archaeological artifacts must be considered in terms of the dynamic cultural and natural processes by which they reached the state in which they are found by archaeologists – rather than as static end products, as they are when a typological approach is used. As with the paleoethnological approach, questions can thus be asked concerning the technological behavior of prehistoric peoples, and one can attempt to situate this behavior within its environmental context (*see* Hunter-Gatherer Societies, Archaeology of). The concept of 'middle-range theory' was borrowed from sociology to provide a link between static archaeological remains and dynamic processes responsible for them. This involves the development of explanatory 'models' based primarily on ethnographic references and experimentation. In addition, processual archeologists placed a new emphasis on the natural formation processes (geological, biological, chemical, etc.) of archaeological sites and objects, as well as on the rigorous application of the hypotheticodeductive method to archaeological interpretation. This led to a more critical view of the ability to interpret the past than that espoused by most European archaeologists, and thus to a divergence of research orientations. In terms of lithic studies, American archaeologists became increasingly concerned with the broader contextual aspects of the objects, including the role of lithic technology within the entire technological system of a cultural group. This approach, known as 'technological organization,' addresses issues such as group mobility, tool design needs and constraints, time allocation, risk factors, and degrees of technological investment (Bamforth and Bleed, 1997; Odell, 1996). It is still the dominant approach followed by American archaeologists today, besides other theoretical or paradigmatic approaches (Bleed, 2001; Hayden et al., 1996; Odell, 2000) (*see* Environmental Archaeology, Ethnoarchaeology, Cognitive Archaeology, and Archaeology, Theory In).

Developments in Technological Analysis and Classification

Simultaneously, and until the present time, continental European archaeologists, the French in particular, continued to develop their inductive approach to lithic artifacts. This perspective is based on profound practical knowledge of Old World lithic industries, whose high variability and informational value (due to an abundance of complex and sophisticated technologies) is particularly well adapted to this type of approach.

As early as 1963, J. Tixier had made the pertinent distinction between method and technique in stone knapping. Technique designates the modes of execution in tool fabrication, including how force is applied (direct percussion, indirect percussion, or pressure), the tool employed (e.g., stone cobble, wood, antler or bone hammer, and copper point), and the gestures that are used (e.g., direction of blow and manner of holding the stone and tools). Method, which is performed according to a systematic and more or less reasoned process, concerns the organization (order and placement) of series of removals from the object being worked, and thus forms the structure of the operational sequence of production. Systematic experiments, which developed largely since then, are essential to the recognition of techniques that can be identified based on particular stigmata seen on the objects (Pelegrin, 2012). In contrast, the knapping method can be identified only through a technological 'reading' of all the objects that entails determination of the direction and order of removals from each piece.

An experienced lithic analyst can mentally perform this technological reading, even in the absence of refit pieces. It is thus possible to classify an assemblage of lithic artifacts according to their original order in the operational sequence of tool fabrication, and distinguish between the products desired by the stone knappers and the waste resulting from their production (Andrefsky, 2009; Inizan et al., 1999–2009).

Economic Perspectives

The analytical principles described above, along with the technological classification of lithic artifacts, have revealed that in certain assemblages particular types of 'blanks' were selected for the fabrication of particular types of tools. This realization led to the concept of debitage economy (economy of the products of knapping). This concept was extended to the end of the operational sequence to include tool economy, via which certain blanks were successively used and/or resharpened in different ways. At the beginning of the operational sequence, in a single lithic assemblage, different stone raw materials were often differentially acquired and/or used. This led to the concept of raw material economy. These perspectives are especially useful for identifying possible choices and decisions made by prehistoric peoples during technological activities (Inizan et al., 1999–2009; Perlès, 1992).

Archaeologists also recognized the need for precise determinations of the geographic origins, and modes of acquisition, of the stone materials found in archaeological sites. Following Renfrew's research on the circulation of obsidian in the Near East, surveys and petrographic characterizations (*see* Archaeometry) were conducted in many regions of the world where

diverse workable stone materials are found. The identification of these materials in prehistoric lithic assemblages allows us to determine the extent of the territories frequented by foragers, from several kilometers for the Early Paleolithic human groups, to several hundreds of kilometers during the Upper Paleolithic (Féblot-Augustins, 2009). Later, during the European Neolithic, stone axes and long blades produced in specialized workshops were exchanged over distances up to 1000 km (e.g., Bradley and Edmonds, 1993). Once neglected, compared to ceramics, the specialized lithic productions from the Neolithic and even 'classical' periods are presently receiving more interest and provide precious information both on social structure (Hayden, 1998) and exchange networks (*see* Trade and Exchange, Archaeology of).

The Development of Methods for Determining the Function of Stone Tools

In 1964, with the English publication of his long-standing research, the Russian archaeologist S.A. Semonov demonstrated that the use of stone tools left different macroscopic and microscopic traces on their surfaces. V.E. Schelinskiï and later L.H. Keeley further developed Semenov's results using a high magnification method that allows for identification of the materials worked (e.g., wet or dry skin, bone, antler, meat, and plants) on the bases of comparison with experimental samples. In addition, lower magnification methods can indicate the manner in which the tool was used (e.g., scraping, drilling, sawing, and striking), and how it was possibly hafted, according to the direction of striations and location of polish and microremovals (Keeley, 1980).

Unfortunately, these time-consuming methods are not completely reliable. Traces of use are quite often damaged, especially on older tools. Another problem is the complexity of the physical processes involved in use wear. Nonetheless, certain important results have been obtained, for example, the illumination of harvesting techniques in the Near East (Anderson, 1999) (*see* Food Production, Origins of). Other studies, also based on experimentation, have focused on confirming the function of stone and bone points as hunting weapon heads. Such analyses attempt to determine how weapon heads were hafted and used (e.g., thrust or thrown by hand, or with a spear thrower or bow, from long or short distance), and test their durability and performance capabilities (Knecht, 1997).

The Evaluation of Skill in Lithic Technology

Stone tool fabrication also can be analyzed in terms of cognitive processes (*see* Cognitive Archaeology). Being an acquired ideomotor activity, stone knapping requires a period of apprenticeship, and involves the operation of certain psychomotor capacities. Research questions such as the following can thus be addressed:

1. The development of psychomotor capacities during the course of human evolution. For example, it has been proposed that the production of bifacial hand axes with regular edges and a symmetrical form, by evolved *Homo erectus*, required a propositional level of reasoning (Pelegrin), and/or Piaget's rational degree of intelligence (Wynn) (Beaune et al., 2009; de la Torre et al., 2003; Gibson and Ingold, 1993; Nowell and Davidson, 2010).
2. The recognition of different skill levels within a Paleolithic human group, indicating the activities of children and adolescents at different stages of apprenticeship, or a sexual division of activities (Pigeot, 1990; Stapert, 2007).

Conclusion

In the past 30–40 years, approaches to lithic artifacts have undergone a genuine revolution. Starting from the former perspective, wherein the most 'characteristic' tools were selected a priori for the purpose of constructing 'chronocultural' sequences, the approaches to lithic technology have become both more refined and broader. They have been refined by considerable progress in methods of technological analysis of individual objects and of assemblages of objects. The development of practical knowledge through experimental analyses has played a major role in this progress. Approaches have broadened due to the ambition of archaeologists to enhance their field as a human science. From a more ecological and social perspective, researchers are interested in tracing the extraordinary diversity of human behavior since the dawn of humanity, and in understanding its underlying evolutionary mechanisms.

Litigation

Herbert M Kritzer, University of Minnesota Law School, Minneapolis, MN, USA

Abstract

Litigation is a highly structured process of dispute resolution that invokes the power of the state, or a contractually agreed-upon private decision-maker, to provide a means to authoritatively adjudicate a dispute between two or more parties. Key theoretical issues for understanding litigation include rights, procedures, incentives, and uncertainty. Rights focus on who has access to litigation and under what circumstances; procedures deal with the processes employed in the litigation process (with a major distinction between adversarial and investigatory procedures); incentives turn on both what can be achieved through litigation and how the costs of employing litigation are determined and distributed; uncertainty reflects the strategic nature of litigation. The frequency of litigation varies among countries, but precise estimates of the quantity or rate of litigation are difficult to determine, due to differences in what is included and what is counted. Litigation is typically conducted through agents (lawyers) who have their own set of incentives. Litigants can be divided into one-shot and repeat players, with the latter enjoying a range of advantages reflecting resources, experience, and time horizon. Litigation procedures are frequently criticized as costly and slow; for these reasons, reform of those procedures occurs with some regularity.

Definition

Litigation is a highly structured process of dispute resolution that invokes the power of the state, or a contractually agreed-upon private decision-maker, to provide a means to authoritatively adjudicate a dispute between two or more parties. In many countries in a large proportion of disputes or cases involving litigation, the parties reach resolutions without completing the full litigation process, either by voluntary settlement, abandonment by one party, or some intermediate authoritative decision short of the full process. Unless there is some legal requirement that the adjudication process be invoked, there is typically an even larger set of disputes that never enter into the formal litigation process but are resolved with the knowledge that the process could be invoked and that anticipate the result the litigation process is likely to produce. Most cases of litigation involve disputes among private parties, either individuals or organizations (businesses, corporations, and so forth). Some cases involve the government as a party to the dispute, and especially in federal systems, the parties on both sides of a case can be governmental entities.

Adjudication involves three key elements: (1) authoritative resolution of a dispute (2) by a neutral third party (3) through the application of preexisting norms or rules. Although the courts customarily are associated with adjudication, there is nothing that limits adjudicatory dispute resolution to courts or other governmental bodies; private adjudication systems are common in many countries and transnationally. Also, while the preexisting norms or rules most often associated with adjudication comprise what is normally called 'law,' there is nothing that precludes adjudication from relying upon any agreed set of norms or rules, including those derived from custom or religious texts.

Litigation is a particular form of adjudication that is based on a set of formalized procedures. Formalization is a matter of degree. There are forms of adjudicative dispute resolution that dispense with most aspects of formalized process; examples include small claims courts, qadi courts, or other kinds of community-based courts. On the formality continuum, there is no clear line separating what is appropriately labeled litigation and what is not.

When a governmental entity serves as the adjudicator and oversees the litigation process, it usually carries the label 'court,' although there are examples where the labels 'commission,' 'tribunal,' 'board,' or 'ombudsman' appear. In some governmental systems, some or all of the courts are formally independent of the other branches of government, while in other systems the courts are more integrated into the executive. Even in systems where the courts are independent of the executive, there are often specialized adjudicatory forums within the executive, possessing varying degrees of independence. What is labeled a 'court' in one system may be labeled a 'tribunal' or a 'commission' in another. For example, in Germany there is a system of 'labor courts' to handle litigation involving many types of disputes arising from the workplace; in Britain some of the cases that would go to labor courts in Germany go to 'Industrial Tribunals,' and in the United States the forum is often called a Labor Relations or Employment Relations 'Commission' or Workers' Compensation Board. Even within a single country one finds entities labeled as 'courts' (the U.S. Tax Court) or as something else ('Tax Appeals Commission'), although both perform similar adjudicatory activities.

For a dispute-resolution process to be a form of litigation requires only that the method of resolution be adjudication, as defined above, and that there is a formalized, structured process governing the forum's activities. Litigation involves a wide range of issues, and the cases range from the most routine, mundane disputes to mega-disputes involving large numbers of people, huge sums of money, or both. Because of this range, generalizations are difficult, and it is best to think in terms of multiple worlds of litigation reflecting differing scales of activities and issues (Hensler, 1993).

Theoretical Issues in Understanding Litigation

The highly structured nature of litigation derives from a combination of rights, procedures, and incentives. Each of

these elements influences who uses litigation, when they choose to use it, and the specific nature of the litigation process.

Rights

Rights refer first to who is granted access to the mechanism of litigation. In the United States and Canada, there are complex rules governing who has 'standing' to bring an action in court, and under what circumstances they may bring that action. For example, under the US Constitution, the jurisdiction of federal courts is limited to 'cases and controversies,' and only those who are in fact affected by the case or controversy may bring an action. In other countries (e.g., Israel or Germany), many kinds of actions can be brought by persons who have only a tangential connection to the harm or the issue in dispute. In still other countries, litigation is used regularly as a means of obtaining advisory opinions from judicial bodies, and there need not be any immediate case or controversy in the American sense.

The legal rules and norms within a country or jurisdiction control the kinds of substantive issues subject to litigation. For example, in England tenants often have what amount to a property interest in their tenancy; this can lead to costly disputes and litigation over whether a property owner can obtain the use of property held under such a tenancy. In the United States, there are very detailed protections afforded certain categories of employees, and there is significant litigation over those protections; in England, there are many fewer specific protections, but a more general limitation on an employer's ability to discharge employees without just cause.

In addition to whether the issues are properly subject to litigation, the question of whether there are avenues of redress other than litigation is important. In England, consumers may bring claims for defective goods, but they may also turn to authorities to enforce criminal laws vis-à-vis the duties of sellers of consumer goods (i.e., consumer protection can be dealt with under criminal law as well as through civil litigation). Despite substantial social and cultural similarities, litigation over torts arising from auto accidents is lower in the Netherlands than in neighboring areas of Germany in part because insurance companies in the Netherlands have institutionalized mechanisms for resolving claims without litigation (Blankenburg, 1998).

The remedies available also have a great deal to do with whether litigation is invoked. In the United States, mass disasters such as fires, airplane crashes, and the like typically result in litigation because American law provides substantial remedies to the victims of such events. In contrast, where remedies are severely limited, litigation is less likely. For example, in 1987, an English cross-channel ferry capsized due to crew negligence, resulting in almost 200 deaths; English law strictly limited damages, and the ferry company and its insurers quickly resolved the victims' claims. A second example of the impact of available remedies involves persons in the United States claiming job discrimination on some basis other than race. Until the early 1990s, civil rights laws limited remedies to lost wages and/or reinstatement; this typically made litigation an unattractive option. In 1991, legislation was passed permitting punitive damages in intentional discrimination cases, making redress through litigation more feasible (Farhang, 2010).

Procedures

A set of rules of procedure govern litigation, whether in a court, an administrative tribunal, or a private setting. These rules determine the form by which litigants initiate claims, provide for mechanisms to inform and establish jurisdiction over defendants or respondents, set procedures for gathering the information necessary for the adjudicator to reach a decision, and establish decision-making rules (standards of proof, who makes the decision, and so forth). Procedural rules also determine the availability of aggregation procedures (e.g., class actions), who bears the burdens of the cost of litigation (i.e., fee shifting), and who actually serves as the adjudicator of issues of fact and issues of law (professional judges, lay juries, or some mixed form). Specific rules may be set by the forum, by the parties, or by some combination of the two, depending upon the structure of the forum. Although there are many variations in specific rules, there are two very broad procedural approaches to litigation that are associated with the two dominant Western legal traditions: common law systems and civil law systems.

Procedure in common law systems is usually based on a model of party adversity, with the adjudicator playing the role of umpire. The parties and their agents have primary control over the flow and process of litigation, with the adjudicator receiving what is offered and forming a decision based on what the parties present. Procedure in civil law systems relies on a model variously described as 'inquisitorial' or 'investigatory,' where the primary responsibility for determining and requesting information lies with the adjudicator. Under the common law system, the formal adjudication tends to be concentrated around an event called a 'trial,' when the two sides present their evidence and witnesses to the adjudicator. Under the civil law system, the formal proceedings are more episodic, with the adjudicator determining what additional evidence or 'proofs' he or she would like to see based on what transpires at a particular session. A second major difference between the two traditions is the relative balance placed on oral versus written processes, with common law procedures traditionally involving a heavier oral component and civil law countries placing a greater emphasis on written materials. Developments in recent years have moved the two systems closer together, with civil systems reducing the episodic nature of adjudication procedures and reducing the reliance on written materials, while common law systems have moved toward increased reliance on written materials.

The specific rules create a basis for analyses of litigation by social scientists. These analyses may be process based, building on the flow of litigation. One approach models litigation as a series of stages and transitions, with litigation progressing from the initial harm through the initiation of a dispute into the formal litigation process, culminating in a trial and possibly an appeal (Felstiner et al., 1980–81; Kritzer, 1991b: pp. 401–402). Other analyses rely on tools such as game theory and economic modeling (e.g., Bebchuk, 1984; Hause, 1989). These latter analyses provide predictions of relative advantages and

disadvantages created by the rules, as well as models of how the parties and their agents should behave under assumptions of economic rationality and uncertainty.

Incentives

Litigation frequently has significant financial implications, in terms of the costs of litigation and/or the resulting remedies. The result is a set of incentives that serve to structure the decision making of the parties and their agents. The first incentive is the likelihood of success, both in terms of 'winning' and in terms of obtaining the desired redress; those who must bear the cost of litigation are sensitive to whether the litigation will succeed. The second incentive is the size of potential remedies, which is a function of the severity of the alleged harm, the law, or rules governing the awarding of remedies (Atiyah, 1987), and possibly the nature of the adjudicator of the remedy (professional or lay, single or group, expert or nonexpert). The third incentive is the costs associated with litigation: institutional fees, costs of representation, and expenses for investigation, experts, and so forth. The fourth incentive is the fee regime governing the payment system for legal representation and associated costs (Kritzer, 2009; Prichard, 1988). A fee regime is defined by three elements: who pays fees and costs, how fees and costs are computed, and how fees and costs are regulated or reviewed. In a number of countries, recent years have seen a range of changes to factors relating to the litigation incentive structure. These changes include limitations on damages that can be obtained ('damage caps'), the adoption of various forms of no win, no pay fees (e.g., 'conditional fees' in England, percentage-based fees in Ontario), the reduction of government-funded legal aid to pay these in some countries, movement away from traditional 'loser pays' rules in England, the development of new forms of insurance such as 'after-the-event' insurance to cover the potential costs payable to the winning party in a 'loser pays' system (Lewis, 2011), and the emergence of third-party litigation finance companies, which essentially fund some or all of a party's costs in return for a share of any recovery (Tuil and Visscher, 2010; Hodges et al., 2012; Shepherd, 2012).

As with procedure generally, incentive structures lend themselves to economic analyses. Extensive formal analyses have been made of rules governing cost allocation and their expected impacts on decisions to litigate, decisions to go to trial or to settle (Reinganum and Wilde, 1986), the likelihood of frivolous litigation (Polinsky and Rubinfeld, 1993), and the role of attorney fee arrangements (Johnson, 1980–81; Shavell, 1982; Hylton, 2012). In addition to theoretical analyses, procedural rules and the resulting incentives have been the subject of extensive empirical analyses, most heavily in the United States but also in England and at least one country on the continent of Europe (Kritzer, 2004; Helland and Tabarrok, 2003; Fenn et al., 2002; Yarrow, 1998; Moorhead, 2010; Faure et al., 2006; Lewis et al., 2006; Morris, 2007).

The Role of Uncertainty

One of the central features of litigation is uncertainty, and the decisions of actors in the litigation system must be made in light of this uncertainty (Bebchuk, 1984; Daughety and Reinganum, 2005). Both the degree and source of uncertainty vary depending on rules, the substance of the case, and the general structure of the system. Key elements of uncertainty include which side the adjudicator will favor, the size or nature of the remedy that the adjudicator will award, the length of time the litigation process will take, and the costs that will be incurred. Part of the uncertainty reflects the strategic nature of all conflict, and part of it reflects the introduction of a third-party, neutral decision-maker, combined with formalized procedures for influencing that decision-maker. Uncertainty creates risk, and the parties involved in litigation differ significantly in their ability and willingness to bear the burdens created by risk (Galanter, 1974).

Empirical Results Concerning Litigation

The most extensive empirical research on litigation has been carried out in the United States, although there is also a growing body of empirical literature focusing on litigation in other common law countries, many European civil law countries, and countries from other regions of the world (Japan, India, the Philippines, and in recent years, China).

Although there is a tendency to speak of litigation as a singular phenomena, there are clearly multiple worlds of litigation (Hensler, 1993). Those worlds can be divided along at least three dimensions: the amount at issue, the types and numbers of parties involved, and the substance of the dispute leading to litigation. Some studies focus on a particular type of litigation (e.g., medical negligence or divorce) while other studies speak in broad terms. Some studies look at prominent cases or sets of cases, such as the litigation surrounding Agent Orange (Schuck, 1986) or the litigation concerning Bendectin (Sanders, 1992), while others focus on routine litigation (Kritzer, 1990) or small claims (Yngvesson and Hennessey, 1975; Vidmar, 1984; Baldwin, 1997). Regardless, one must be careful to take note of the types of cases being examined and avoid drawing general conclusions about litigation based on a study that looks at only a slice of the broad litigation phenomenon.

The Likelihood that Disputants Will Turn to Litigation

Research from a variety of countries consistently has shown that relatively small proportions of most disputes eventually involve formal litigation procedures (Genn, 1999; Pleasence et al., 2010; Murayama, 2007; Michelson, 2007). The exceptions involve certain types of cases that by law require formal court action (e.g., dissolution of marriage in many countries), but those types of cases frequently involve only *pro forma* court action. Particularly in common law countries, the image of the filtering process has often been cast as a 'Disputing Pyramid,' with injuries occupying the base of the pyramid and final adjudicatory resolution at the top (Engel and Steele, 1979; Miller and Sarat, 1980–81). The base of the pyramid is broad and the upper areas are narrow; most of the variation, whether by type of dispute or by country, tends to come in the middle regions of the pyramid, reflecting a combination of incentive structures and alternative avenues of redress.

The initiation of litigation presupposes that an injury is perceived, that responsibility for the injury is externalized, and

that a grievant (or an agent of the grievant) seeks redress (Felstiner et al., 1980–81). Most research shows substantial attrition from potential claims to actual claims (Kritzer, 2010), often reflecting that injured parties are never aware that they have suffered an injury, do not attribute to someone else the responsibility for the injury, or do not initiate a claim because of a belief that redress is not practical or it is not needed given alternative sources of compensation. As suggested above, even if litigation is initiated, most cases end before final adjudication. Settlements occur in what has been dubbed the 'shadow of the law' (Mnookin and Kornhauser, 1979), and they reflect anticipations of what judges or juries will decide.

In common law countries, the emphasis in the civil justice process is on proof provided by the parties; in civil law systems, the emphasis is on logical reasoning by the judge. Thus, in civil law countries, the adjudicator plays a more central role, and multilevel review is a more integral and usual part of the process. As a result, there are many more adjudicators in civil law countries. Moreover, the perceived quality of judges making the initial decision is lower in civil law countries compared to common law countries, where the numbers of judges are relatively small and are chosen selectively after years of legal practice. In civil law countries, it is relatively easy to get an initial court decision because the judge controls the process; in common law countries, obtaining an initial court decision is more difficult and costly because the parties can fight each other every step of the way. However, in civil law countries, appeals are more common, making the economic advantage of one system over another unclear.

Cross-National Patterns in Litigiousness

The United States has a reputation as particularly litigious. This in part reflects the important role played by law and courts in the United States from its inception. However, one study that attempted to generate litigation rates *c.*1990 across a wide

Figure 1 Litigation rates, *c.*1990. Wollschläger, C., 1998. Exploring global landscapes of litigation rates. In: Jurgen Brand and Dieter Strempel (Eds.), Soziologie des rechts: Festschrift für Erhard Blankenburg zum 60 geburtstag. Nomos Verlagsgesellschaft, Baden Baden, pp. 577–588.

range of countries cast doubt on that reputation (Wollschläger, 1998). Figure 1 graphically represents the findings of that study and shows substantial variation in the use of litigation. While the United States is at the higher end of the distribution, it does not stand out as exceptional. However, caution must be exercised in interpreting the information in Figure 1 (and in Figure 2, which will be discussed later) because of the difficult issues that arise in estimating litigation rates across countries.

A first general problem with comparing litigation rates is obtaining comparable information across countries. Countries, and even subunits of countries, differ in institutional arrangements for dealing with various types of problems. For example, in Germany there is a separate group of labor courts to deal with a range of workplace issues; in England, these types of matters are routed to industrial tribunals rather than to courts. In the most states of the United States, claims arising from workplace injuries go to administrative tribunals, but there are a small number of states that have established workers' compensation courts. Tax disputes may go to an administrative body, to a specialized tax court, or in some situations to a general jurisdiction court. A further complication is that in some countries many civil matters that come to court are not litigious; separating out the litigious and nonlitigious matters presents a challenge.

There has been an effort among a range of European countries to develop a system of reporting on those countries' judicial

Figure 2 European litigation rates, 2004–10. Reports published by the European Commission for the Efficiency of Justice (CEPEJ).

systems to allow for a measure of comparison (Contini, 2000). The European Commission for the Efficiency of Justice has issued four reports providing estimated litigation rates for 2004, 2006, 2008, and 2010, covering as many as 49 countries in Europe. Figure 2 shows the range of litigation rates reported for each of the 49 countries, with the lighter bar showing the maximum rate reported (or the single rate where only one report was available) and the darker bar showing the minimum rate. For a few countries, it is clear that some change occurred in what was being reported (i.e., the litigation rate for England and Wales was on the order of 3500 per 100 000 population for the first two reports but dropped to less than 550 per 100 000 for the last two reports). Figure 2 is striking for the variation among the European countries, and the inconsistency with patterns in Figure 1. According to Figure 1, Germany was the most litigious of the European countries *c*.1990, followed closely by Sweden and Austria; Spain and the Netherlands stood at the bottom of that figure among European countries. In contrast, Figure 2 puts the Netherlands as third-most litigious and Spain in the top half, with Sweden close to the bottom and Germany in the middle.

A second general problem with comparing litigiousness is determining the baseline that should be used. Almost all studies rely on per capita litigation rates. However, litigation arises out of very specific types of events, the number of which is not simply a function of population. For example, product liability litigation arises from events involving products that are purchased; a country with a higher rate of material consumption may have a higher per capita rate of product liability litigation simply because the transactions that might give rise to such litigation are more common. The problem of using baselines other than simple population is almost never addressed because of the difficulties of developing workable alternatives.

Many explanations have been suggested for whatever variation actually exists. Japan is frequently cited as a country with a very low litigation rate. One explanation for this is that within Japanese culture there is an imperative to avoid conflict (Kawashima, 1973). An alternative explanation is that events such as automobile accidents are dealt with in a way that avoids the need for litigation (Tanase, 1990). A third explanation is that the Japanese elite has intentionally restricted access to litigation as a form of redress; this may be starting to change with the decision in Japan to increase the number of lawyers (*bengoshi*) who are authorized to bring court cases.

The Role that Litigants and Their Agents (Lawyers) Play

Decisions to initiate litigation typically are made by litigants in consultation with their legal advisors. Two elements dominate the decision to litigate. The first is the need to finance the litigation. The second is the likelihood of success, both in terms of whether the desired decision can be obtained and whether the decision will be enforceable. Research has shown consistently that a key element in obtaining redress in tort cases is the availability of a source of payment, either a wealthy defendant or insurance coverage.

Where the potential litigant must directly finance the litigation, the decision to initiate litigation will lie almost entirely with the potential litigant. Lawyers may seek to dissuade potential litigants from pursuing the claim, citing the financial, time, and emotional costs as well as the uncertainty inherent in the process. Where the cost, or at least the risk, of the litigation is to be borne by some other actor, these actors will typically be more involved in the decision to proceed. For example, in the United States, where much litigation is funded by plaintiffs' lawyers through the mechanism of a contingency fee, the lawyer's decision whether to accept a case is crucial; lawyers turn down at least as many cases as they accept (Kritzer, 2004; Daniels and Martin, 2002). When some third party, such as an insurance company (through litigation expense insurance), legal aid, or a trade union, will cover the litigation expense, the third party will make the decision on whether to proceed or require that it be allowed to review and veto any decision to proceed. These decisions are determined by a combination of likelihood of success and the amount at stake.

Nature of Litigants

The nature of litigants typically varies depending on the type of case. Tort (injury) cases are dominated by individuals as plaintiffs, while contract cases more often involve businesses as plaintiffs. Defendants in tort cases are often nominally individuals, but most individual defendants are insured and the insurance company becomes the effective defendant. In contract cases, defendants are distributed among individuals and organizations, with variations depending on the exact nature of the issue at stake.

Litigants are not created equal. Litigation typically requires resources and expertise, and analysts have argued that this conveys an advantage to the wealthy. Galanter (1974) distinguished between "one-shot" and "repeat players" in litigation, arguing that the repeat players, who tend to be 'haves,' should be expected to win more often than the 'one-shotters,' who are likely to be 'have-nots.' While some of the advantages of repeat players reflect resources, other advantages reflect the ability of the repeat player to take a long-run view of litigation. The result is that repeat players are more able to 'play the odds' (i.e., they can act as risk-neutral participants), and more able to 'play for rules' (i.e., try to establish precedents that will work to their advantage over the long run). Galanter's distinction has been examined in a significant body of research conducted in a range of countries (Glenn, 2003).

The importance of the one-shot versus repeat player distinction for understanding how litigants behave is further enhanced by dividing the repeat player into the 'government player,' which may have even fewer economic constraints than other repeat players and which may play by a set of special rules, and the 'routine player,' for whom litigation is genuinely a part of doing business (e.g., the liability insurance company) and which cares little about the outcome of individual cases as long as it is able to comfortably predict the likelihood of winning and losing. Yet another type of repeat player is the political interest group, which uses litigation for explicitly political purposes. Although this is most often discussed in the American context (Kagan, 2001; Silverstein, 2009), it is by no means unique to the United States; particularly as politics becomes more judicialized (Harlow and Rawlings, 1992; Tate and Vallinder, 1995; Kelemen, 2006), these types of litigants are becoming both more common and more important. Developments such as the increasing role of the European

Court of Justice reflect and encourage these changes. Notably, although there has been an increase in interest group litigation, the evidence is inconsistent on whether interest group involvement increases the likelihood of success (Epstein and Rowland, 1991) or whether interest groups actually achieve their ultimate goals even when successful in court (Rosenberg, 1991; Hall, 2011).

Litigation Process

Research on the process of litigation is generally nation specific, because the process is so closely tied to the rules governing that process. Some of the research focuses on the handling of specific types of cases, such as injury cases or divorce cases. Much of this research focuses on the role of the lawyer in the litigation process (Kritzer, 1990) and how lawyers relate to their clients (Rosenthal, 1974; Sarat and Felstiner, 1995); there is disagreement over the degree to which lawyers dominate in the decision-making process (Kritzer, 1998). Other studies focus on specific aspects of litigation, including the impact of specific rules and procedures such as discovery (Brazil, 1980b, 1980a; McKenna and Wiggins, 1998; Mullenix, 1994; Willging et al., 1998), summary judgment (Cecil et al., 2007; Eisenberg and Lanvers, 2009; Kritzer, 1986), the declining incidence of trials (Galanter, 2004; Dingwall and Cloatre, 2006), the rules regarding expert testimony (Cecil, 2005; Edmond, 2008; Cheng and Yoon, 2005; Gatowski et al., 2001), the role the judge in settlement processes (Provine, 1987; Robinson, 2009; Galanter and Cahill, 1994), and procedures and problems in aggregating claims (Hensler et al., 2009). Recent changes in the United States regarding pleading standards in the federal courts are beginning to generate research on how those changes may be impacting the litigation process (Cecil et al., 2011; Moore, 2012). There is no theoretical framework or argument tying together this disparate research, which is heavily US-based.

One area that is ripe for cross-national research is the impact of fee regimes, given that there is more variation in those regimes across countries than within countries. However, any cross-national research on this topic confronts a range of confounding factors that make isolating the impact of the elements of fee regimes extremely difficult. The most successful research has relied upon internal variation in fee regimes (Fenn et al., 2002) or natural experiments arising from changes in fee regimes (Snyder and Hughes, 1990; Hughes and Snyder, 1995). England and Wales are particularly fertile grounds for research in this area, given the changes that have occurred since 1995, when conditional fees were first permitted (Fenn et al., 2002; Yarrow, 1998; Moorhead, 2010; Lewis et al., 2006; Morris, 2007). It is too early to know whether research on the impact of these changes will heighten our empirical understanding of the impact of fee regimes on the litigation process.

Winning and Losing in Litigation

A natural issue in the study of litigation concerns the outcome: who wins, who loses, and why? The definition of winning and losing is problematic: should outcomes be measured in absolute terms or relative terms? If a plaintiff (the initiator of litigation) obtains some redress from the court, has the plaintiff 'won'? What if that very same result could have been achieved without litigation, and what if what the plaintiff sought was something more that it failed to achieve? What if the only reason it could have achieved even that lesser result was because the option of litigation existed? With relatively few exceptions, studies of litigation outcome ignore these complications. A second problem is that the final resolution of litigation is most often a private agreement among the parties. Those cases resolved through formal, final adjudication tend to be a small, nonrepresentative subset. Some scholars argue that the cases resolved through trial are those where uncertainty is high or where there are strongly conflicting views of the likely outcome (Priest and Klein, 1984). Others argue that some types of parties avoid adjudicatory outcomes intentionally when the result will produce unfavorable results, and concentrate their adjudicatory efforts on cases that will produce favorable precedential outcomes (Galanter, 1974).
